INTRODUCTION

The Klamath Tribes have been monitoring water quality parameters in Upper Klamath Lake (UKL) since 1990. These data have been described and summarized to varying degrees in a series of reports and manuscripts (e.g., Kann 1998; Kann and Smith 1999; Kann and Welch 2005; Kann 2007 through Kann 2011). The UKL electronic water quality database was previously updated with 2011 data and appropriate quality assurance analyses (*see Excel spreadsheet: Klamath Tribes UKL Water Quality Data 1990-2011.xls*). A recent report provides additional detail on the 1990-2009 database (Jassby and Kann 2010). The current 2011 report is intended to serve as an annual update to the UKL water quality database, including a summary of 2011 data (basic summary statistics and graphical analysis), and limited comparison of inter-annual trends of UKL data collected for the 22 year period between 1990 and 2011.

METHODS

Methods followed the Klamath Tribes established procedures for field collection and laboratory analysis of water quality parameters (see Klamath Tribes 2003 and Klamath Tribes 2006 for a complete description of these methods). Beginning in 2008 for nutrient parameters and 2009 for Chlorophyll-a (CHL), laboratory analyses transitioned from Aquatic Research, INC. in Seattle WA to the Sprague River Water Quality Laboratory in Chiloquin OR. During the transition period duplicate samples were analyzed by both laboratories to confirm parameter reproducibility. During the 2011 sampling season limnological data (Table 1) were collected biweekly from the end of April through October at 10 standardized stations in UKL and Agency Lake (Figure 1; Figure 2).

Table 1. Limnological parameters sampled in Upper Klamath Lake, 2011.

Parameter	Abbreviation/ Unit	Profile [a]	Grab [b]
Temperature	T (^oC)	X	
Dissolved Oxygen	DO (mg/L)	X	
pH	pH	X	
Specific Conductivity	(µSiemens/cm)	X	
Secchi Transparency	Secchi (m)		
Light (Photosynthetically Active Radiation)	PAR ($uEm^{-2}s^{-1}$)	X	
Total Phosphorus	TP (µg/L)		X
Soluble Reactive phosphorus	SRP (µg/L)		X
Total Nitrogen	TN (µg/L)		X
Ammonia Nitrogen	NH_4-N (µg/L)		X
Nitrate-Nitrite Nitrogen	NO_3+ NO_2-N (µg/L)		X
Chlorophyll *a*	CHL (µg/L)		X
Phytoplankton Species Composition and Biomass[c]	(mm^3/L)		X
Zooplankton Species Composition and Biomass[c]	(mg/L)		X

a Profile = collected with multi-parameter WQ probe at multiple depths in water column
b Grab = integrated water column sample collected with "tube sampler" except for zooplankton which was collected with a Schindler-Patalis Trap
c. Phytoplankton and zooplankton data are compiled in spreadsheets provided separately and are not analyzed herein.

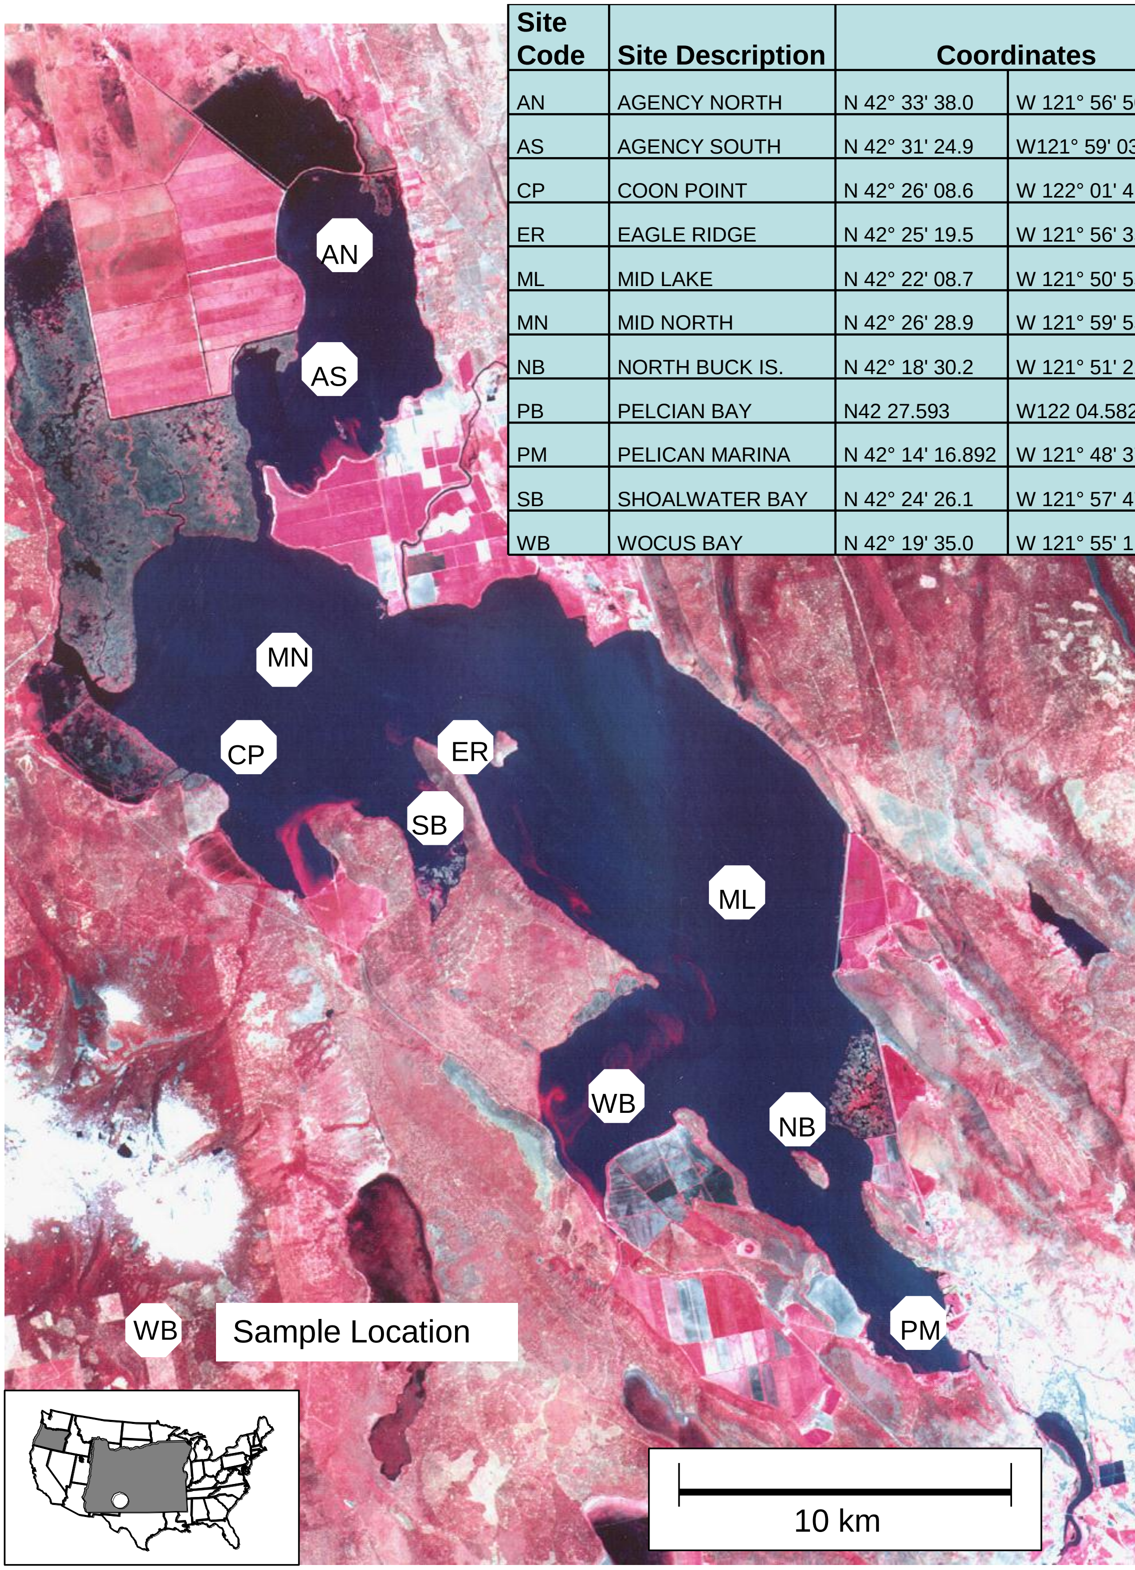

Figure 1. Location of Upper Klamath Lake sampling stations, 2011.

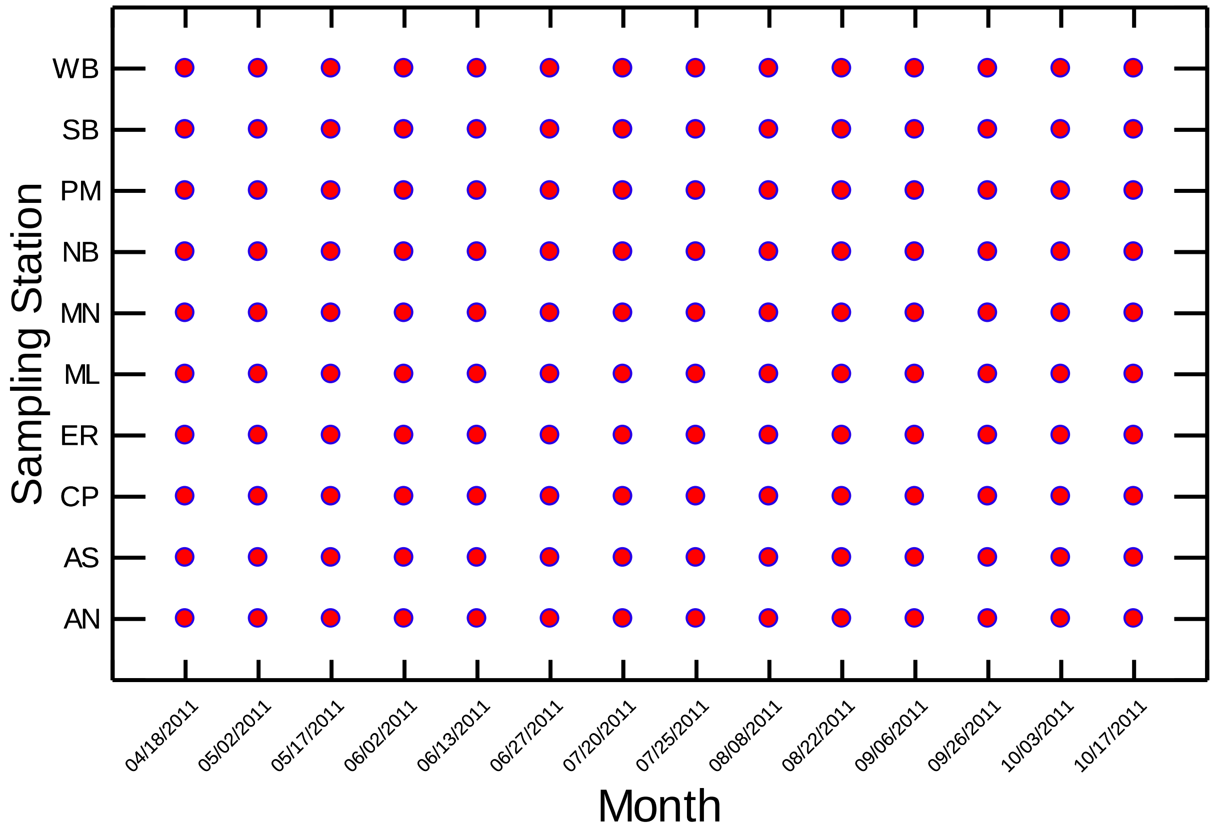

Figure 2. Spatial-temporal sampling matrix for Upper Klamath Lake, 2011

Data reduction consisted of computation of both lake-wide means on a given sample date and of growing season (June-September sample dates) means. Because of bloom timing differences between Upper Klamath and Agency Lake (e.g., see Kann 1998), lake-wide means and analyses are shown separately for Upper Klamath Lake only and Agency Lake only. Chlorophyll and nutrient data tended to be either normally or log-normally distributed both within a date and seasonally. Based on a comparison of both log transformed ($\log_{10}$ or $\log_{10}$ (x+1)) and non-transformed data with the normal distribution using Kolmogorov-Smirnov one-sample tests or the Shapiro-Wilk standard test for normality (*cf.* Systat® 2004), the geometric mean tended to provide the best estimate of lake-wide or seasonal central tendency.

Nutrient quality assurance/quality control analyses are shown in the accompanying data spreadsheet (*Klamath Tribes UKL Water Quality Data 1990-2011.xls)*

RESULTS/DISCUSSION

Seasonal and Water Column Trends in Profile Water Quality Data (T, DO, and pH)

Water column and seasonal trends in T, DO, and pH are important aspects of water quality dynamics and fish habitat in UKL. Depth-time plots of isotherms and isopleths for these parameters allows both seasonal and depth distribution to be evaluated simultaneously. These are plotted below for two representative stations, ER located in the deep trench area, and MN located in an open-water area in the northern part of the lake (Figure 3; Figure 4). At both stations temperature ranged between 8-10 ^{o}C during late-April and early-May, with little additional warming occurring into mid-May and early-June when temperatures generally remained below 12 ^{o}C. Although significant warming then occurred during the first half of June, temperatures still remained below 18 ^{o}C, and only rose slightly to <20 ^{o}C through the 3rd week in July. Water temperature then increased again in late-July, before peaking during the mid-August period (Figure 3; Figure 4). Maximum surface and water column temperatures occurred during the early-August to early- September period, with seasonal cooling beginning in early-September when a temperature drop of 2 ^{o}C occurred (from ~22 to <20 ^{o}C).

Unlike 2010 when water column pH initially increased (>9.0) in late-April and early-May (lake observations at that time indicated a massive diatom bloom and further confirmation showed very high biomass of the diatom *Asterionella formosa*), pH in 2011 remained relatively low (<8.5) until late-June. A sharp increase to seasonal peak values then occurred by late-July with values ranging between 9.5-10.0 (Figure 3; Figure 4). Aside from Agency Lake (data not shown) which continued to increase into early-September, UKL stations generally declined through the remainder of the season. Similar to 2009 and 2010, pH maxima were not in sync with the period of maximum water column temperature, although in 2011 the pH peak occurred prior to seasonal peak temperature rather than after as in 2009 and 2010.

Water column DO values were initially elevated in late-April and early-May (10-11 mg/L), and declined in mid-May (8-9 mg/L) at which time they continued to decline overall until late-June (7-8 mg/L). Although surface DO then increased slightly (>10 mg/L; coinciding with the pH increase in late-July), DO at lower depths remained near 7 mg/L (Figure 3 and Figure 4). DO then declined during early-August to early-September at deeper depths (4-5 mg/L), especially at ER (Figure 3). As shown below, trends in pH and DO can be largely explained by temperature and algal dynamics (cool late-spring and early-summer conditions were associated with low algal productivity, a delayed bloom, and moderate bloom decline). Similar depth-time plots were constructed for these stations for all years of data (1990-2011) and are shown in Appendix I.

Although a comprehensive inter-annual analysis will not be performed here, 2011 water column temperatures showed a later peak than most years (early August as opposed to late-July), DO tended to be moderate to low on a water column-wide basis, but did not show the extreme lows indicative of severe bloom declines, and the pH seasonal peak tended to be lower than most other years, especially deeper in the water column (Appendix I). As shown below and earlier data and analytical reports (e.g., Kann 2011; Jassby and Kann 2010) differences in pH and dissolved oxygen can be explained partly by the interaction of both climate and bloom dynamics.

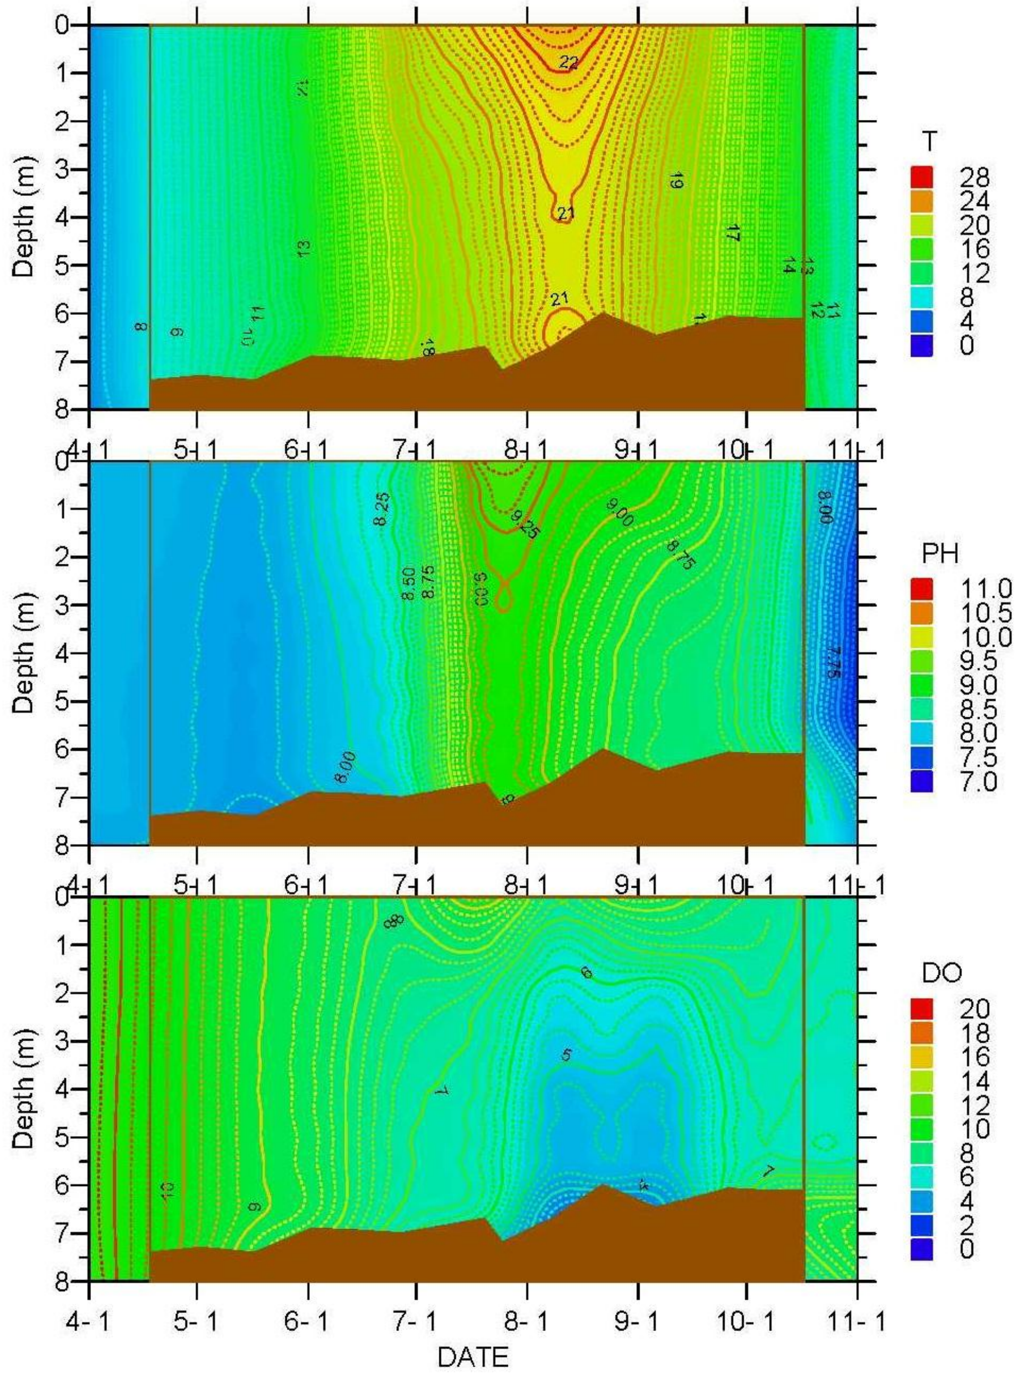

Figure 3. Depth-time distributions of isotherms of T (oC) and isopleths of D.O (mg/L) and pH at UKL station Eagle Ridge (ER), 2011. Note: 1) brown shaded area on the abscissa denotes the bottom profile depth, and 2) contours are not valid outside of vertical brown lines (begin and end dates for seasonal sampling).

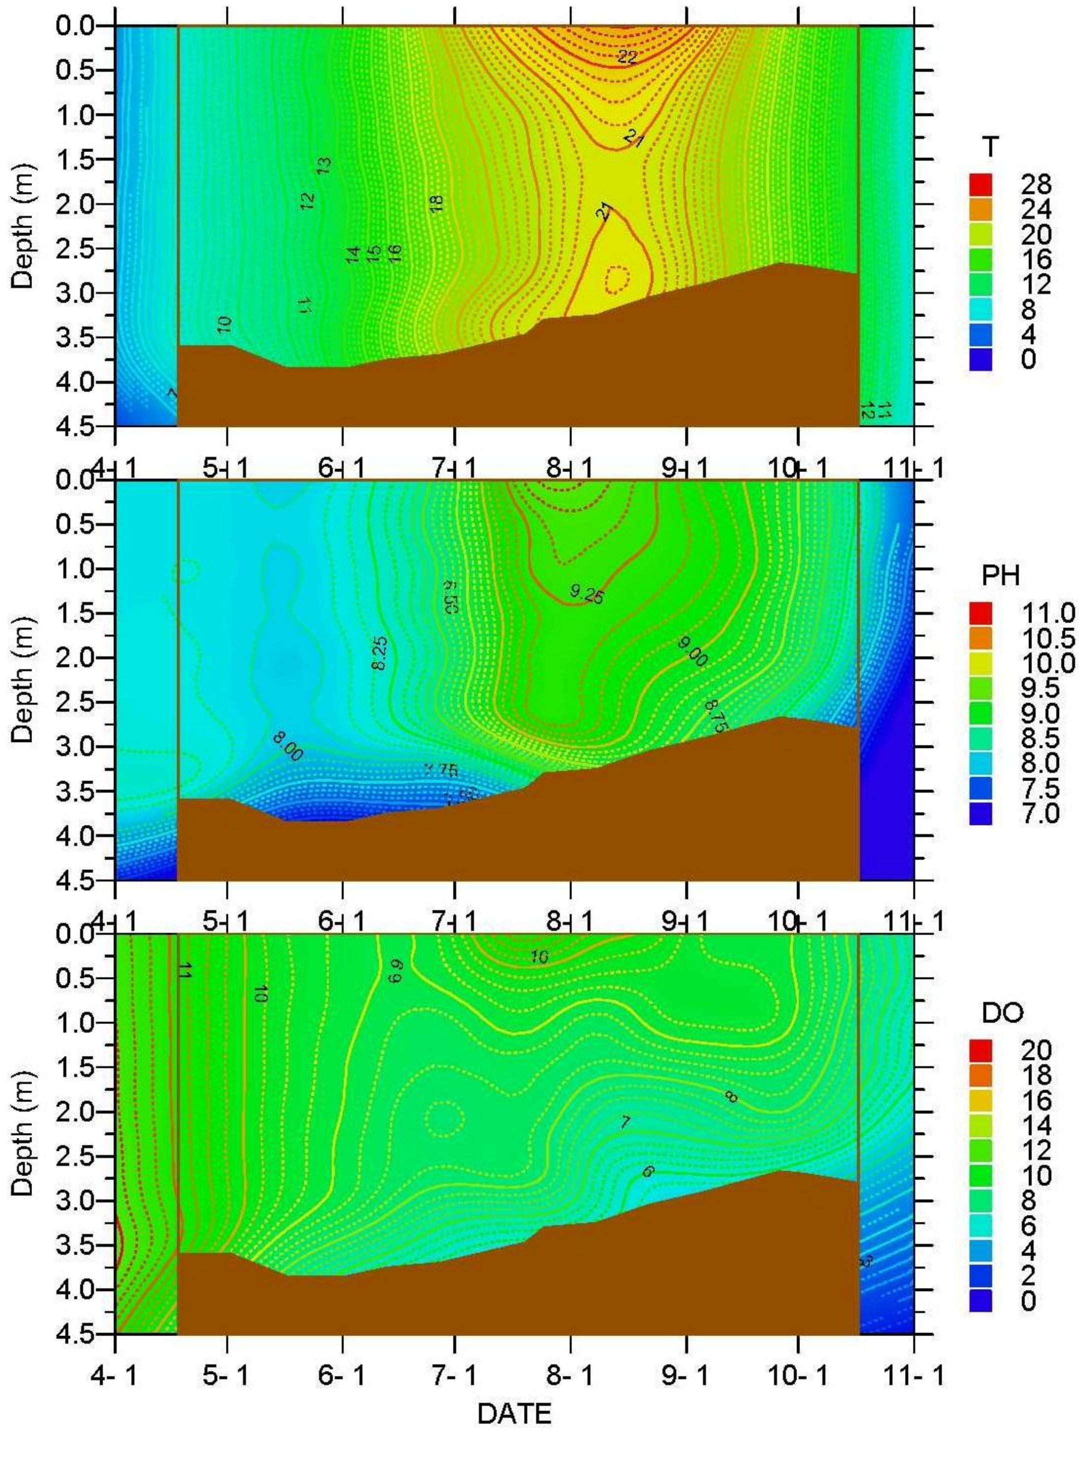

Figure 4. Depth-time distributions of isotherms of T (˚C) and isopleths of D.O (mg/L) and pH at UKL station Mid North (MN), 2011. Note: 1) brown shaded area on the abscissa denotes the bottom profile depth, and 2) contours are not valid outside of vertical brown lines (begin and end dates for seasonal sampling).

2011 Station Distributions

The distribution of parameter values for each station for the June-September period (chosen here to encompass the major algal growing season in UKL) are shown in Figure 5 and Figure 6. Although the seasonal timing of water quality has been shown to vary among stations (see below analyses comparing individual stations by date), the season-wide distributions as indicated by the interquartile range (25^{th}-75^{th} percentiles or box hinges in the plots below) tend to overlap for most parameters. In addition, although the timing of sample collection can affect the distribution of these variables (particularly temperature, pH and dissolved oxygen), the below plots reflect water column means which are less sensitive to the effect of sample timing than are surface values.

Nonetheless, as with previous years, certain stations tended to stand out on a seasonal basis. For example, the pH distribution (as indicated by the upper or lower quartile) was skewed higher for WB and AS (and to a lesser degree AN and ML), and skewed lower for ER and NB (Figure 5). ER showed the lowest overall DO, while the remaining stations were not appreciably different, although AS, AN, and WB showed slightly higher upper quartile values. Secchi depth (transparency) was notably lower only at WB and higher at ML and CP. These among-station comparisons were not necessarily consistent with 2010 patterns (see Kann 2011), and aside from ER and WB, among-station patterns appear to vary year-to-year.

Embayment stations SB and WB, along with station MN were among the highest with respect to median CHL, and ML, CP , AS, and AN among the lowest (Figure 6). However, the inter-quartile CHL range was similar among many other stations. As in 2010, the AS and AN stations stand out with noticeably higher upper quartile and median values for TP and SRP, and WB for TP (Figure 6).

Similar to previous years, Agency Lake stations were among the lowest for nitrogen, particularly for NH_4-N, but also for NO_3-N (Figure 6; Table 2). The upper quartile value for TN was highest at WB, while the interquartile range was highest at SB. Similar to 2010, ER, SB, and CP were among the highest for ammonia, although MN was also relatively high in 2011 (NH_4-N; Figure 6; Table 2). Un-ionized ammonia also tended to be highest at ER, SB, and CP in 2011 (Figure 6). NO_3-N was higher overall at NB. Overall nitrogen patterns differed slightly from 2010, but were similar to 2008 and 2009.

Seasonal differences in algal biomass (CHL) among stations in 2011 show that, similar to 2010, 2009 and 2008, but unlike 2006 (Kann 2011) and 2007 when AS and AN increased earlier and declined earlier in the season relative to UKL stations (Figure 7); early season CHL in Agency Lake was low in late-April and early-May and was then similar to UKL for much of the remainder of the season (Figure 7). However, there still appeared to be a tendency for CHL at the Agency Lake stations to decline earlier than UKL stations in 2011. The similarity between Agency and UKL Lakes in terms of the June algal biomass increase and seasonal maxima and decline in the later years may reflect greater connectivity between the two lakes due wetland restoration activities on the Williamson Delta Preserve (e.g., Wong et al. 2010; 2011). CHL concentration at the more southerly stations vs. northerly stations did not tend to show a similar seasonal pattern to previous years when relatively higher CHL occurred later in the bloom cycle (e.g., August) at the southerly stations.

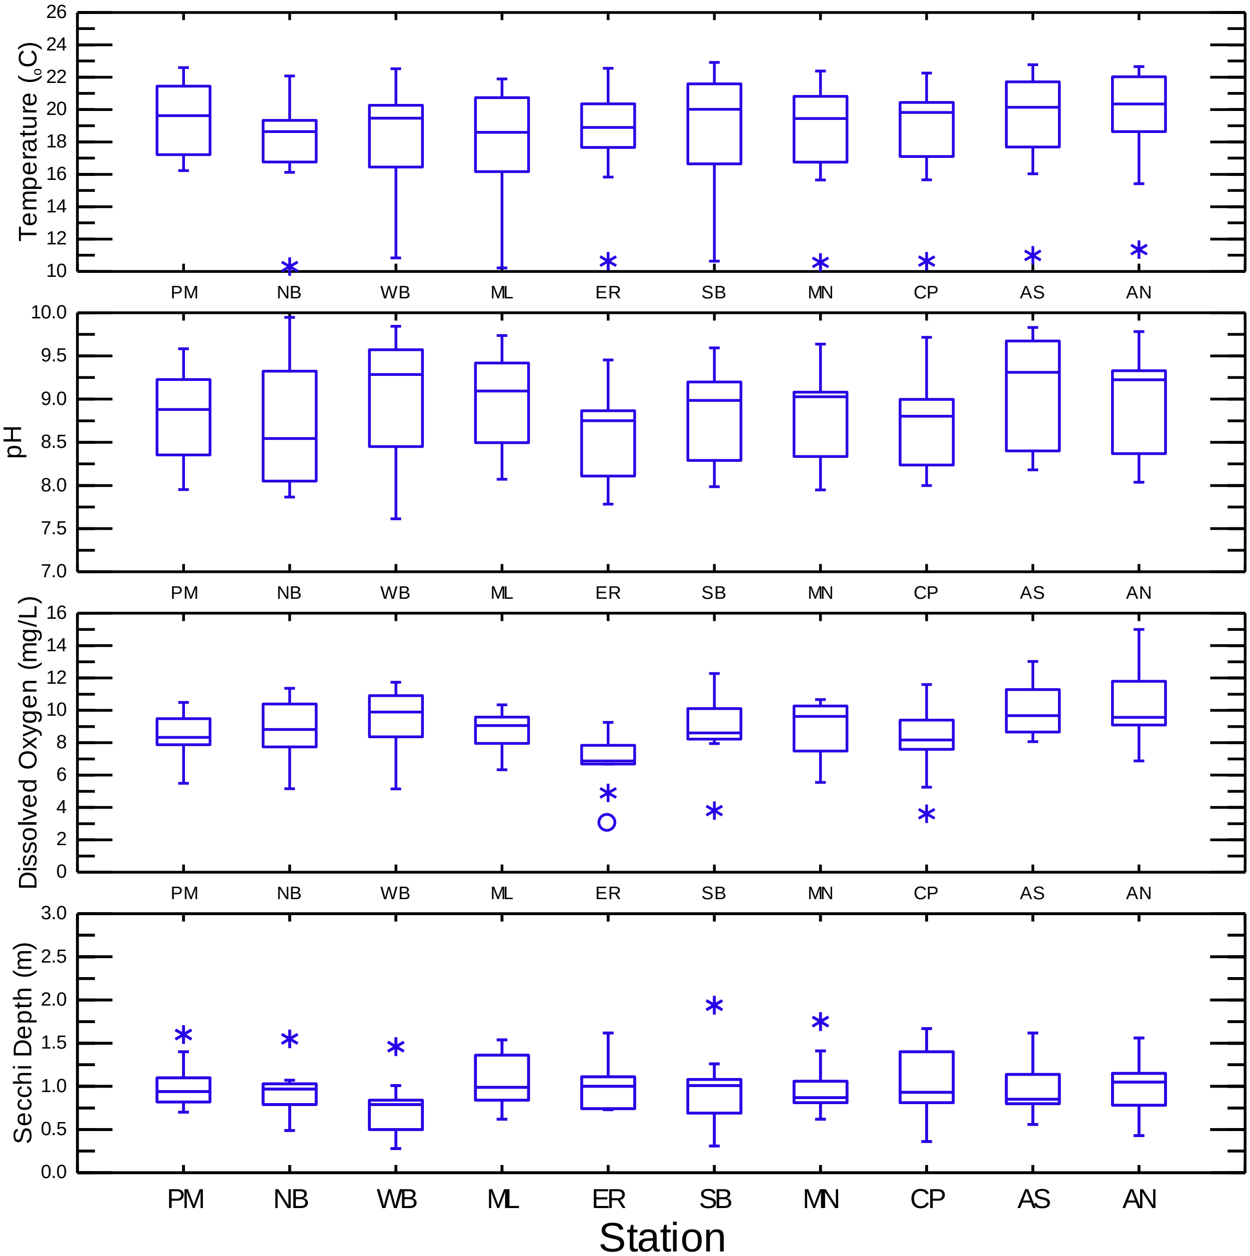

Figure 5. Station distributions of T (˚C), pH, D.O (mg/L), and Secchi depth, June-September, 2011.

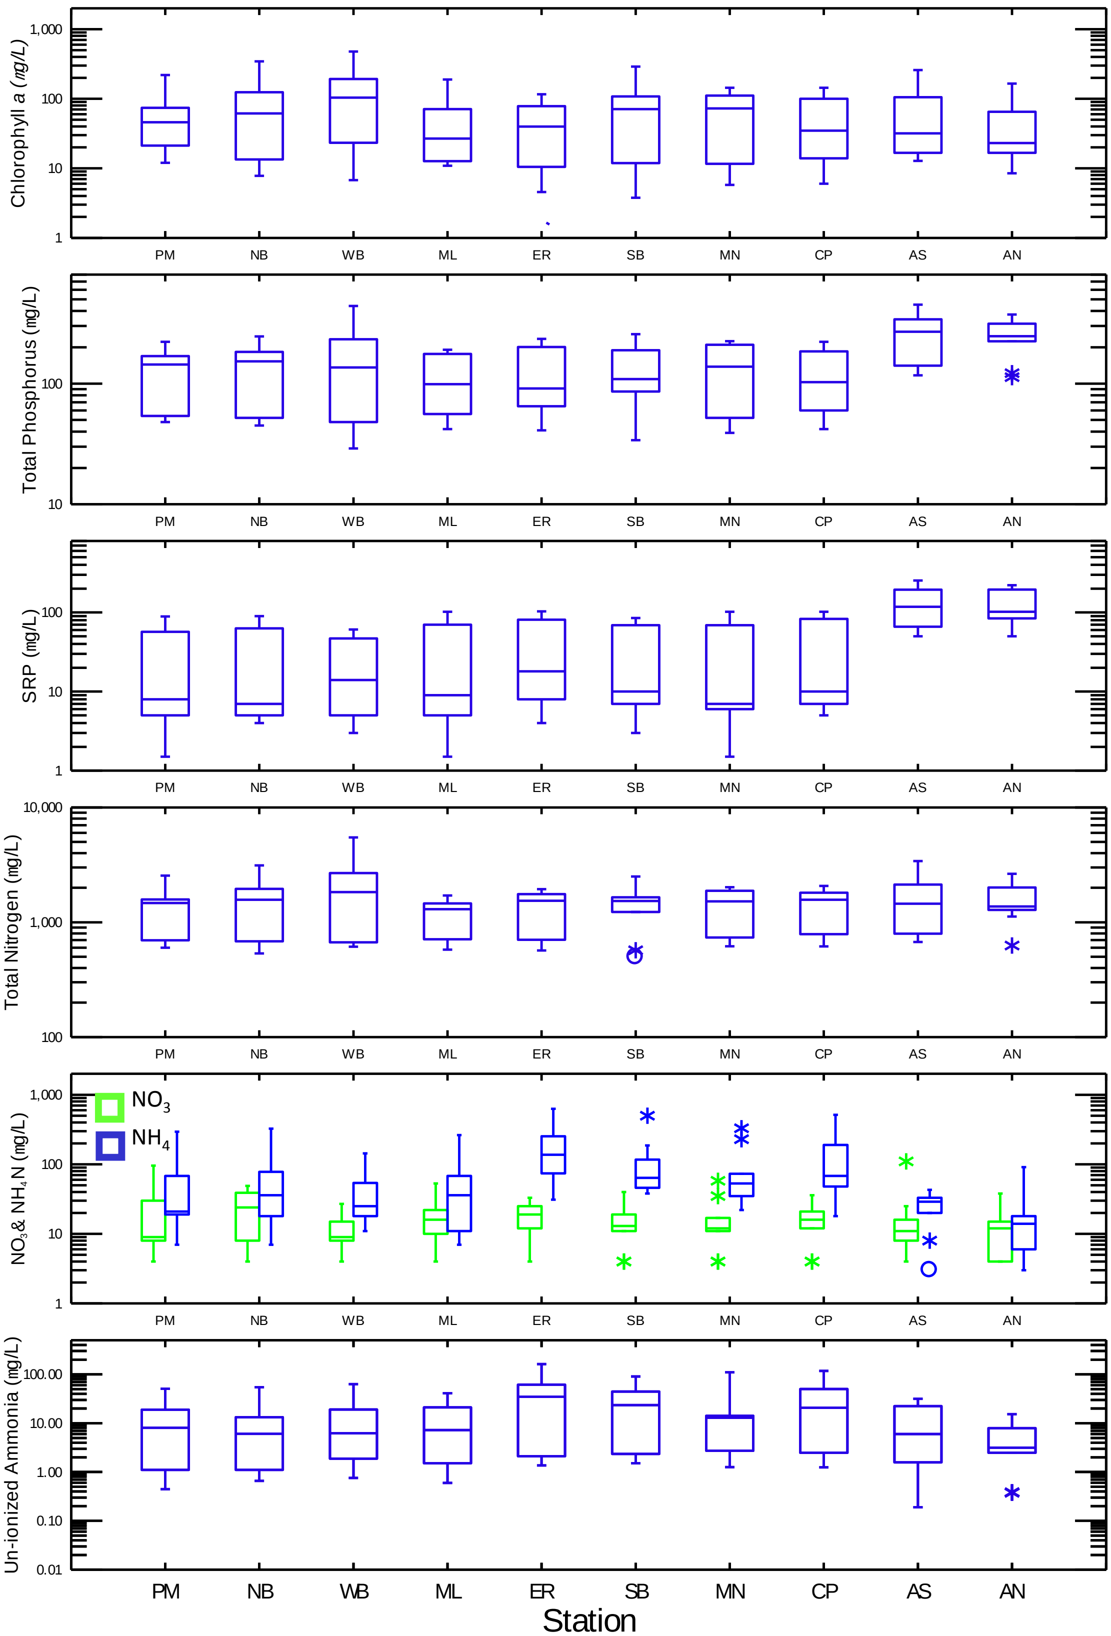

Figure 6. Station distributions of CHL, TP, SRP, TN, NO_3+ NO_2-N, NH_4-N, and un-ionized ammonia, June-September, 2011.

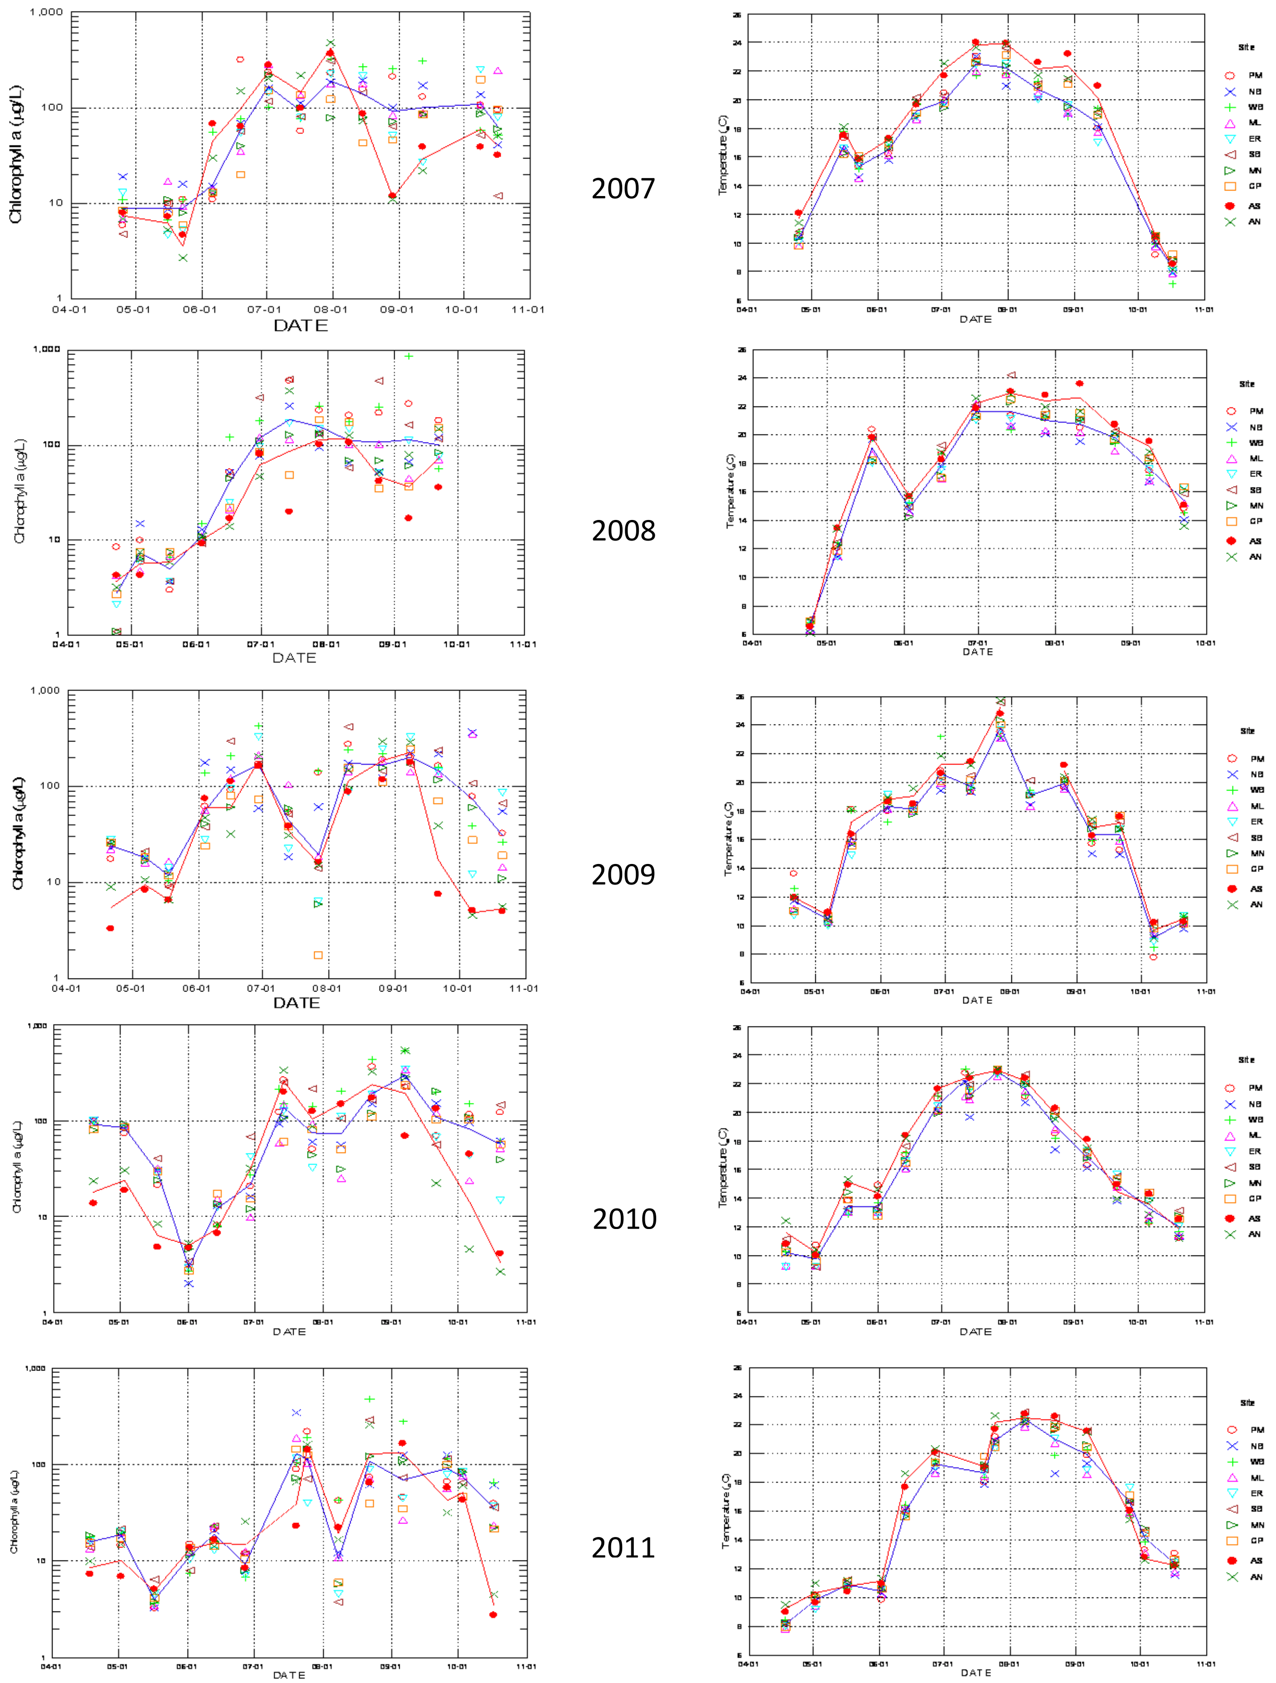

Figure 7. Seasonal CHL and temperature trends for UKL stations, 2007-2011 (blue line shows the median value for UKL-only, red line shows the median value for Agency Lake-only).

Seasonal Chlorophyll Pattern and Climate Interaction

As noted in previous annual reports (Kann 2008 to 2011), water temperature partially explained the early season CHL patterns among the years. For example, low temperatures coincided with a depressed early-June bloom in 2006, and in 2008 much cooler lake-wide water temperature (median value <7 ^{o}C) in late April and early-May also coincided with low CHL levels. However, it was clear that factors other than temperature were affecting bloom dynamics in those years (Figure 7).

For example, in 2010, late-April and early-May CHL was noticeably higher than the previous four years (generally >80 µg/L) due to an unusually large diatom bloom (*Asterionella formosa*) occurring at that time– despite temperatures in a range similar to many of the previous years (Kann 2011). The large 2010 diatom bloom then declined rapidly beginning in mid-May and by early-June chlorophyll levels were less than 10 µg/L. In contrast, CHL levels in 2011 were only slightly elevated in late-April and early-May (generally <20 µg/L), and except for a decline in mid-May (<7 µg/L), they remained generally less than 20 µg/L (often less than 10 µg/L at many stations) through the end of June (Figure 7). During this same period water column temperature remained very cool (<11 ^{o}C through early June) and although mid-June temperature increased to ~16 ^{o}C in UKL (they were 1-2 deg. warmer in Agency Lake), they only rose slightly, remaining <20 ^{o}C through most of July (Figure 7). In contrast, water temperatures during the previous five years generally exceeded 20 ^{o}C by early-July, if not sooner (Figure 7).

Because water temperature in the above plots is measured biweekly, and due to UKL's shallow depth a short lag-time is generally observed with respect to equilibrium with ambient air temperatures (e.g., Wood et al. 2006), it is also instructive to evaluate daily air temperatures as another indicator of water column warming. Hourly data obtained from the USBR AgriMet station located near Agency Lake (Figure 13a) indicated at least partial tracking of May air temperature and CHL levels (Kann 2011). For example, temperature declines in mid-May of 2006 and 2008 that remained near or below 15 ^{o}C through mid-June were associated with suppressed CHL levels in early-June (Kann 2011). In 2007 and 2009, air temperatures warmed between mid- and late-May and were associated with elevated CHL levels in early June, and in 2010, when temperatures cooled substantially in mid-May and portions of June, CHL also remained suppressed during early and mid-June (Figure 7; Figure 8a).

Air temperature in 2011was similar to other years in the beginning of May, but unlike other years it remained relatively constant through May (it was also among the lowest when compared to previous years and showed further cooling towards the end of May) before increasing in June to levels similar to other years (Figure 8a). A significant departure from other years then occurred in July of 2011 when the upper quartile, median, and lower quartile values of daily mean air temperature were substantially lower than corresponding values for the previous 5 years (Figure 9).

In general, previous analyses indicating a threshold temperature of ~15 for *Aphanizomenon* bloom development in Upper Klamath Lake (Kann 1998; Kann 2011) continue to be supported. However, as noted previously (Kann 2011) high CHL levels due to spring diatom blooms can be achieved even at temperatures much cooler than 15 ^{o}C. Furthermore, based on 2011 patterns it appears that once the 15 ^{o}C threshold was reached, cool temperatures towards the end of June and into July also had an apparent effect on continuing algal biomass development.

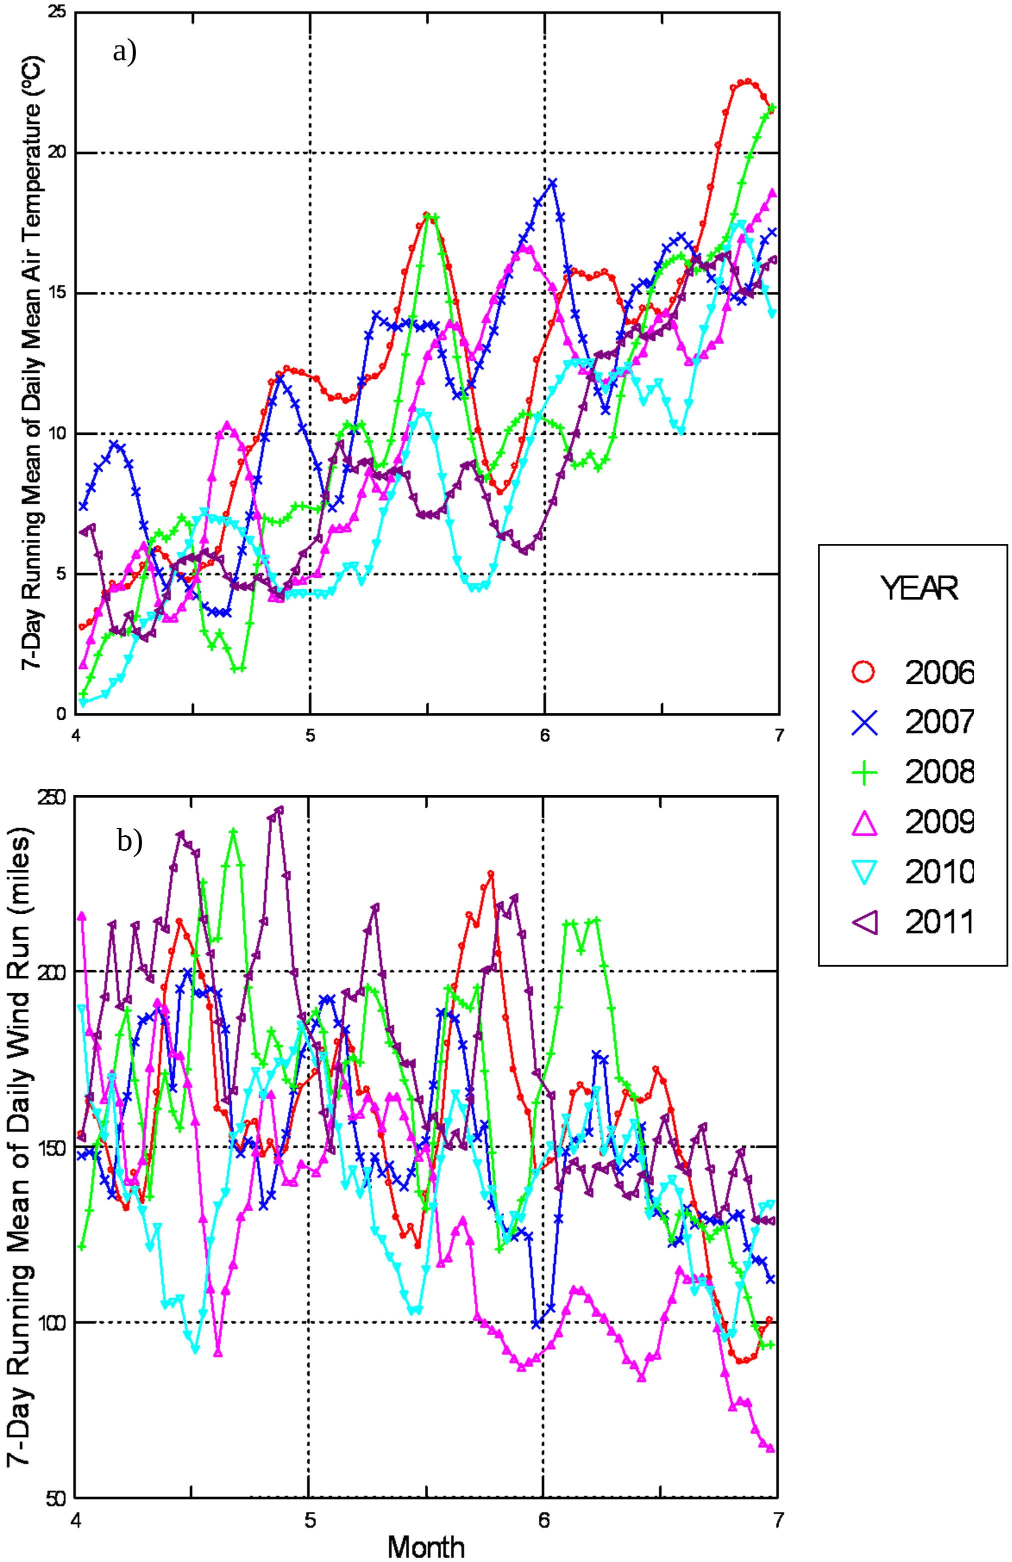

Figure 8. Time series of the 7-day running mean of daily air temperature (a) and 7-day running mean of the daily wind run in miles (b), April-June, 2006-2011. Data are from the Bureau of Reclamation AgriMet station located at Agency Lake (AGKO).

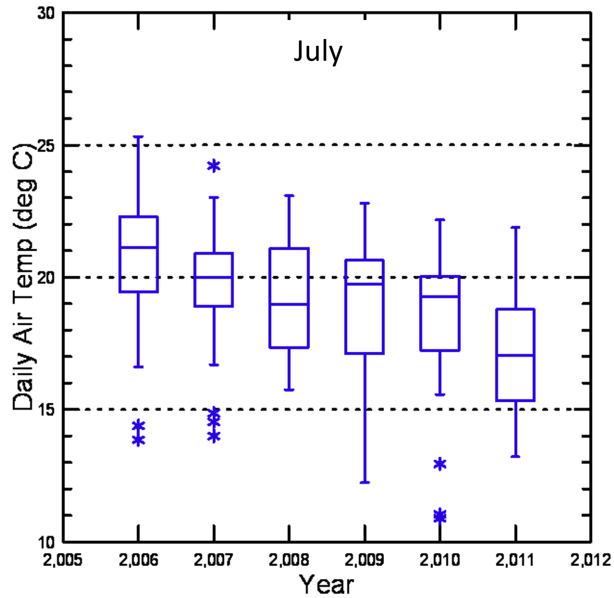

Figure 9. Annual distribution of Agency Lake AgriMet (AGKO) daily air temperatures during July, 2006-2011.

Analysis of wind speed as an indicator of the extent of water column mixing showed that the periods directly preceding and during the typical period of June bloom development in 2006 and 2008 (which had relatively low CHL during that period) were characterized by generally higher wind speed relative to 2007 (Figure 8b), which had relatively higher CHL (Kann 2011). Wind speed during 2009 was more similar to 2007 (which had lower wind preceding and during development of the early June bloom), and also tended to have relatively higher CHL compared to 2006 or 2008, which were suppressed. The pattern for 2010 was less clear and may have been confounded by the massive diatom bloom which crashed immediately preceding the June period when *Aphanizomenon* typically begins to increase. Although wind was somewhat low to intermediate during the typical bloom initiation period in 2010 (late-May to early-June; Figure 8b), CHL still remained suppressed, possibly reflecting the unusually cool period occurring during late-May (Figure 8a). Likewise, in 2011 relatively high wind speeds in April and May were associated with relatively low algal biomass (Figure 8b).

Also similar to previous 2006-2010 analysis of air temperature and wind speed data that showed wind and temperature to be related such that warm/calm conditions co-occur and that cool/windy conditions co-occur (Kann 2011), these parameters also tended to co-occur in 2011(Figure 10). Supporting observations from the above time-series graphs, confidence ellipses computed for the period encompassing 10 days prior to and subsequent to June 1st (the typical period of initial *Aphanizomenon* increase) show that both 2006 and 2008 (red and green ellipses in Figure 10) tended to be cooler and windier than during the same periods in 2007 and 2009 (blue and pink ellipses). 2009 showed the lowest wind speed of the four years (Figure 8b and Figure 10) and was associated with higher early- and mid-June CHL than the other years (Figure 7) (Kann 2010). Temperatures in 2010 were cooler overall than the other years and

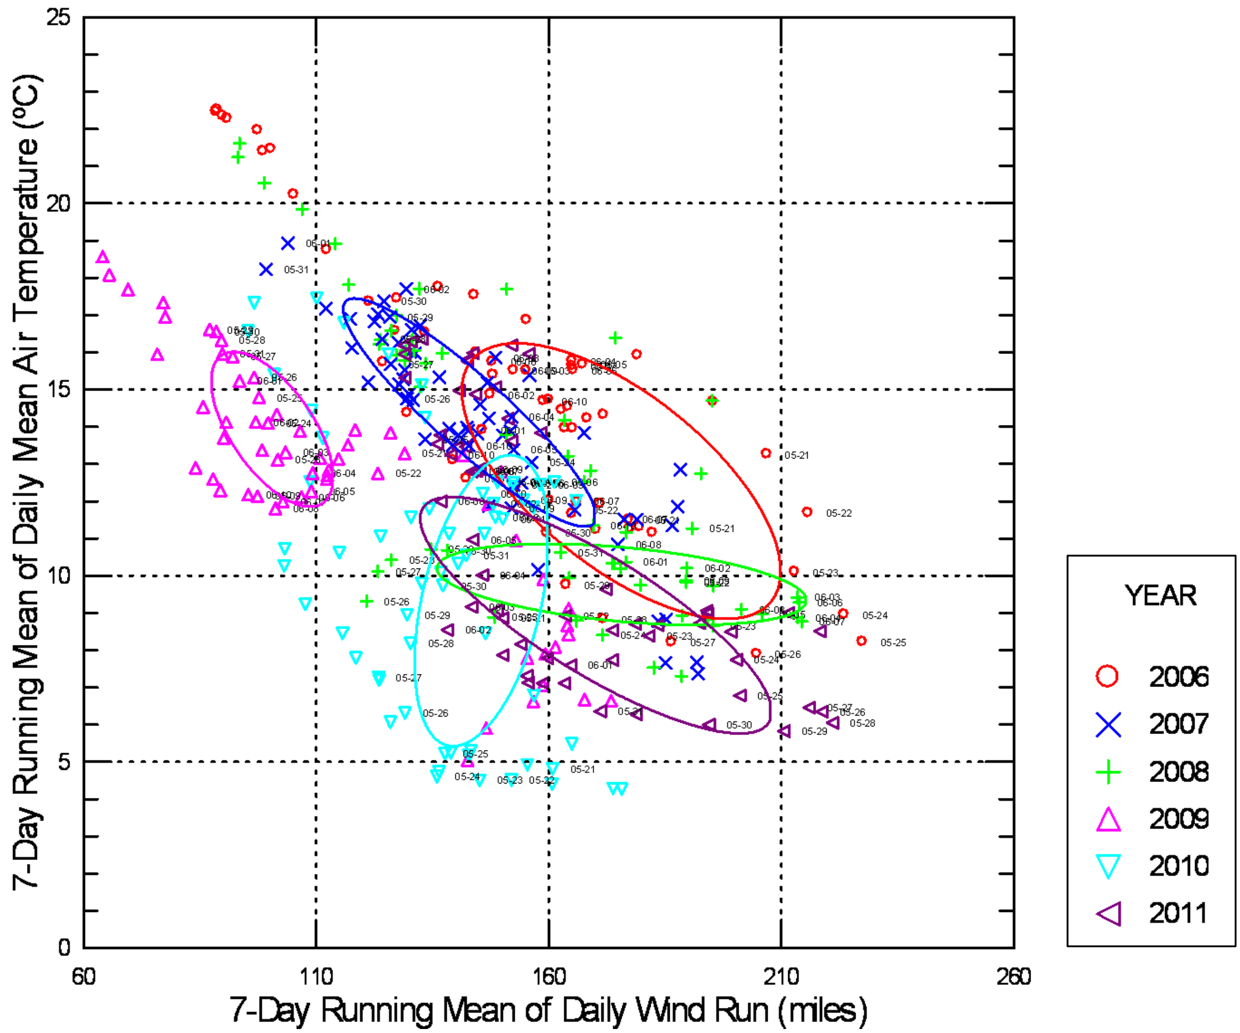

Figure 10. Scatter plot of the 7-day running mean of the daily wind run (miles) vs. 7-day running mean of daily air temperature (ºC) during May and June. Data are from the Bureau of Reclamation AgriMet station located at Agency Lake (AGKO). Data labels are day of the month. Confidence ellipses are drawn for dates occurring during the last 10 days of May and first 10 days of June; confidence ellipses are centered on the sample means of the x and y variables where the unbiased sample standard deviations of x and y determine its major axes and the sample covariance between x and y, its orientation (Systat 2011).

wind speeds were only intermediate (Figure 10). During 2011the late-May to early-June period was among the coolest and windiest of the six years portrayed (Figure 10), and as noted above also showed relatively low algal biomass levels.

These climate data indicate that cooler and well mixed conditions during the usual early season bloom development period (e.g., Kann and Welch 2005) help explain year-to-year bloom development. Multivariate analyses performed on the longer 1990-2009 data set also showed that wind and temperature, along with lake elevation were determinants of CHL levels in UKL (Jassby and Kann 2010). As noted below these factors also interact with varying year-to-year variability in nutrient concentrations.

2011 Monthly and Seasonal Water Quality, Chlorophyll, and Nutrient Patterns

Basic statistics for monthly distributions for all sampling years are shown in Appendix 1. Peak water temperatures occurred in August of 2011 compared to the more typical pattern of July (Figure 11). Monthly distributions for pH in 2011 were similar to 2006-2008 which showed a progressive seasonal increase with seasonal maxima occurring in July that coincided with the lowest Secchi depth (indicating reduced transparency) and highest CHL distributions (note that in 2010 high pH values occurred in April, declined in May and June and showed a bimodal peak in July and September). Although CHL rebounded somewhat in late-August and September of 2011 (Figure 7 and Figure 12), pH continued to decline and did not show a bimodal peak (Figure 11). Lower DO occurred during August in 2011, and although the timing was similar to other years, DO was not as low as when more extended bloom declines occurred. As noted above, CHL exhibited a second peak but lake-wide values were generally <100 µg/L during September of 2011 (Figure 12).

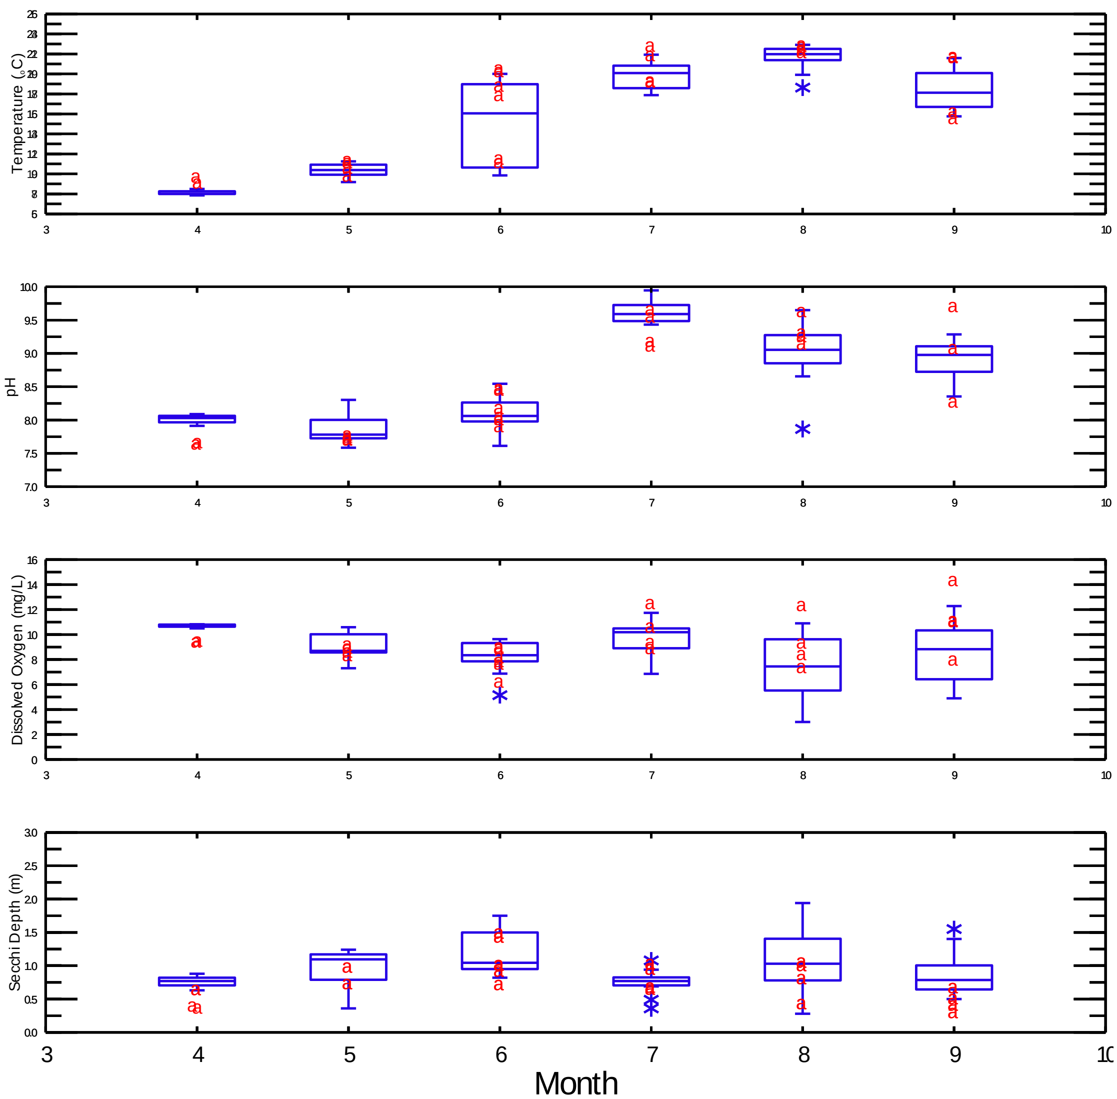

Figure 11. Monthly distributions of T (˚C), pH, D.O (mg/L), and Secchi depth, 2011 (symbol "a" denotes values for Agency Lake plotted separately from the box plot distribution).

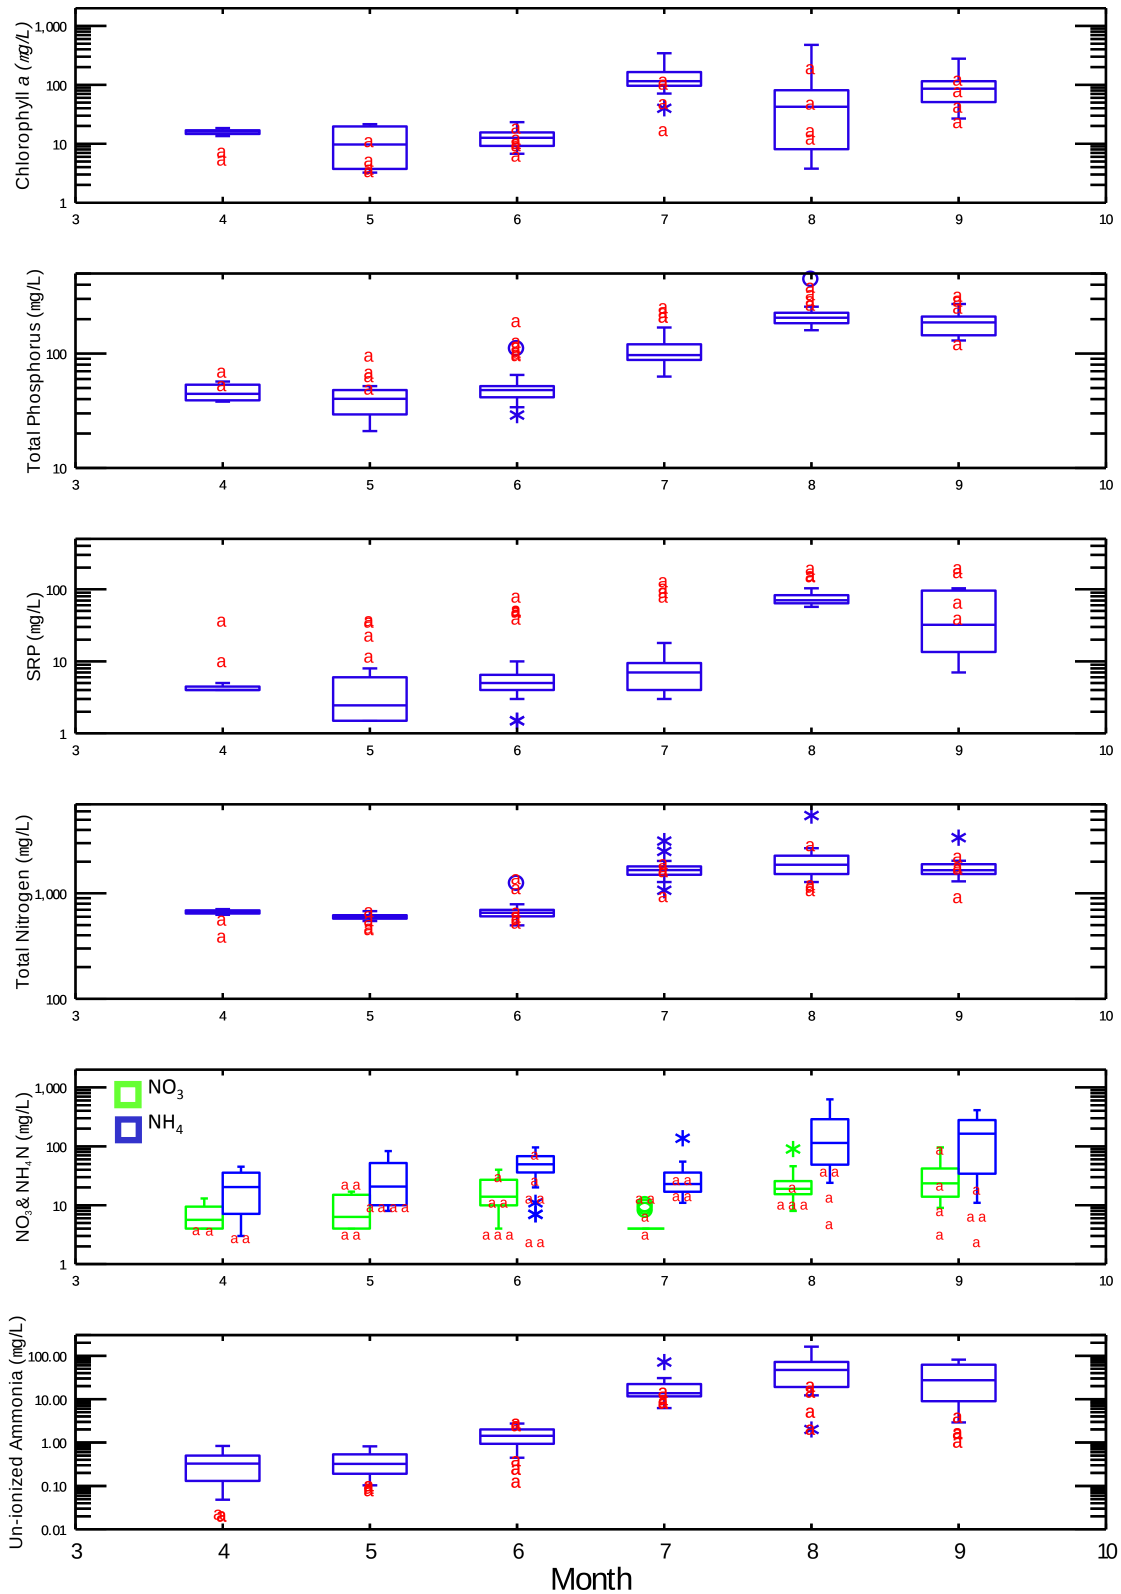

Figure 12. Monthly distributions of CHL, TP, SRP, TN, NO3+ NO2-N, NH4-N, and un-ionized ammonia, 2011 (symbol "a" denotes values for Agency Lake plotted separately from the box plot distribution).

TP and SRP in 2011 remained low and relatively constant through June before TP increased in July during the overall CHL increase (Figure 12). Although TP and TN typically increase during June, values remained low for both parameters during June of 2011, with values then increasing during July when CHL increased with the initiation of the *Aphanizomenon* bloom. Showing about a month delay when compared to the typical seasonal pattern, SRP, $NO_{3,}$ and $NH_{4,}$ remained low and relatively constant though July before increasing in August (Figure 12).

A further look at the 2011 time-series with respect to CHL and dissolved nutrients shows that, as in other years, SRP at the UKL stations remained low through the initial July CHL peak before increasing during the algal biomass decline in early August (Figure 13). Also as in previous years (e.g., 2009 and 2010), this trend did not apply to the Agency Lake stations which showed elevated SRP in April (AN) and May (AN and AS), with levels then increasing and remaining high during the July CHL increase (Figure 13). As noted previously, there is an indication that SRP may be limiting the early season bloom in UKL (in the case of 2011 the early season bloom occurred in July), especially since internal sources of phosphorus are also increasing during that time period (Kann 2010; Walker et al. 2012).

In previous years TIN (the sum of NH_4-N and NO_3-N) levels were relatively low during the spring period, and although levels in 2011 were also relatively low compared to later in the season they tended to be somewhat elevated when compared to previous years (Figure 13). These relatively higher TIN levels (as well as climate) may play have played a role in suppressing the June to early-July *Aphanizomenon* bloom (Figure 13). Levels were notably lower on a lake-wide basis during the period leading up to the 2010 bloom (Figure 14). Similar to SRP, TIN then increased substantially during the August CHL decline (Figure 13). As in 2009 and 2010, both SRP and TIN in 2011 tended to decline as CHL underwent a second growth phase in late-August. Spring and fall TIN tended to show an increased proportion of NO_3-N, while summer TIN was comprised predominantly of NH_4-N (Figure 13).

Both 2010 and 2011 showed ratios of TN:TP during April to be ~15, which in general would tend to favor the type of diatom blooms observed in spring (Figure 14). However, unlike 2010 when the TN:TP and TIN:SRP ratios declined in May and June during the period preceding the rise of nitrogen-fixing *Aphanizomenon* in UKL (TN:TP ratios were generally lower than 12 and TIN:SRP<2.5), ratios increased substantially during 2011, especially for TIN:SRP (values were greater than 15 in early July; Figure 14). This increase appears to be driven by the higher TIN values during his period, and as noted above may provide a partial explanation for the late onset of the nitrogen-fixing *Aphanizomenon* bloom.

An apparent geographical grouping of stations occurred in 2011 (Figure 13); Agency Lake stations (higher early-season SRP and TP and higher SRP overall); northerly stations MN, CP, SB, ER (higher TIN during the August bloom crash and extending into October); and southerly stations ML, WB, NB, PM (somewhat lower TIN during the August bloom crash, and increase in September, and low levels in October). As noted above differences in magnitude and timing of CHL at the Agency Lake stations are not as apparent as in earlier years, possibly due to dike breaching and greater connectivity between the two lakes (Figure 12).

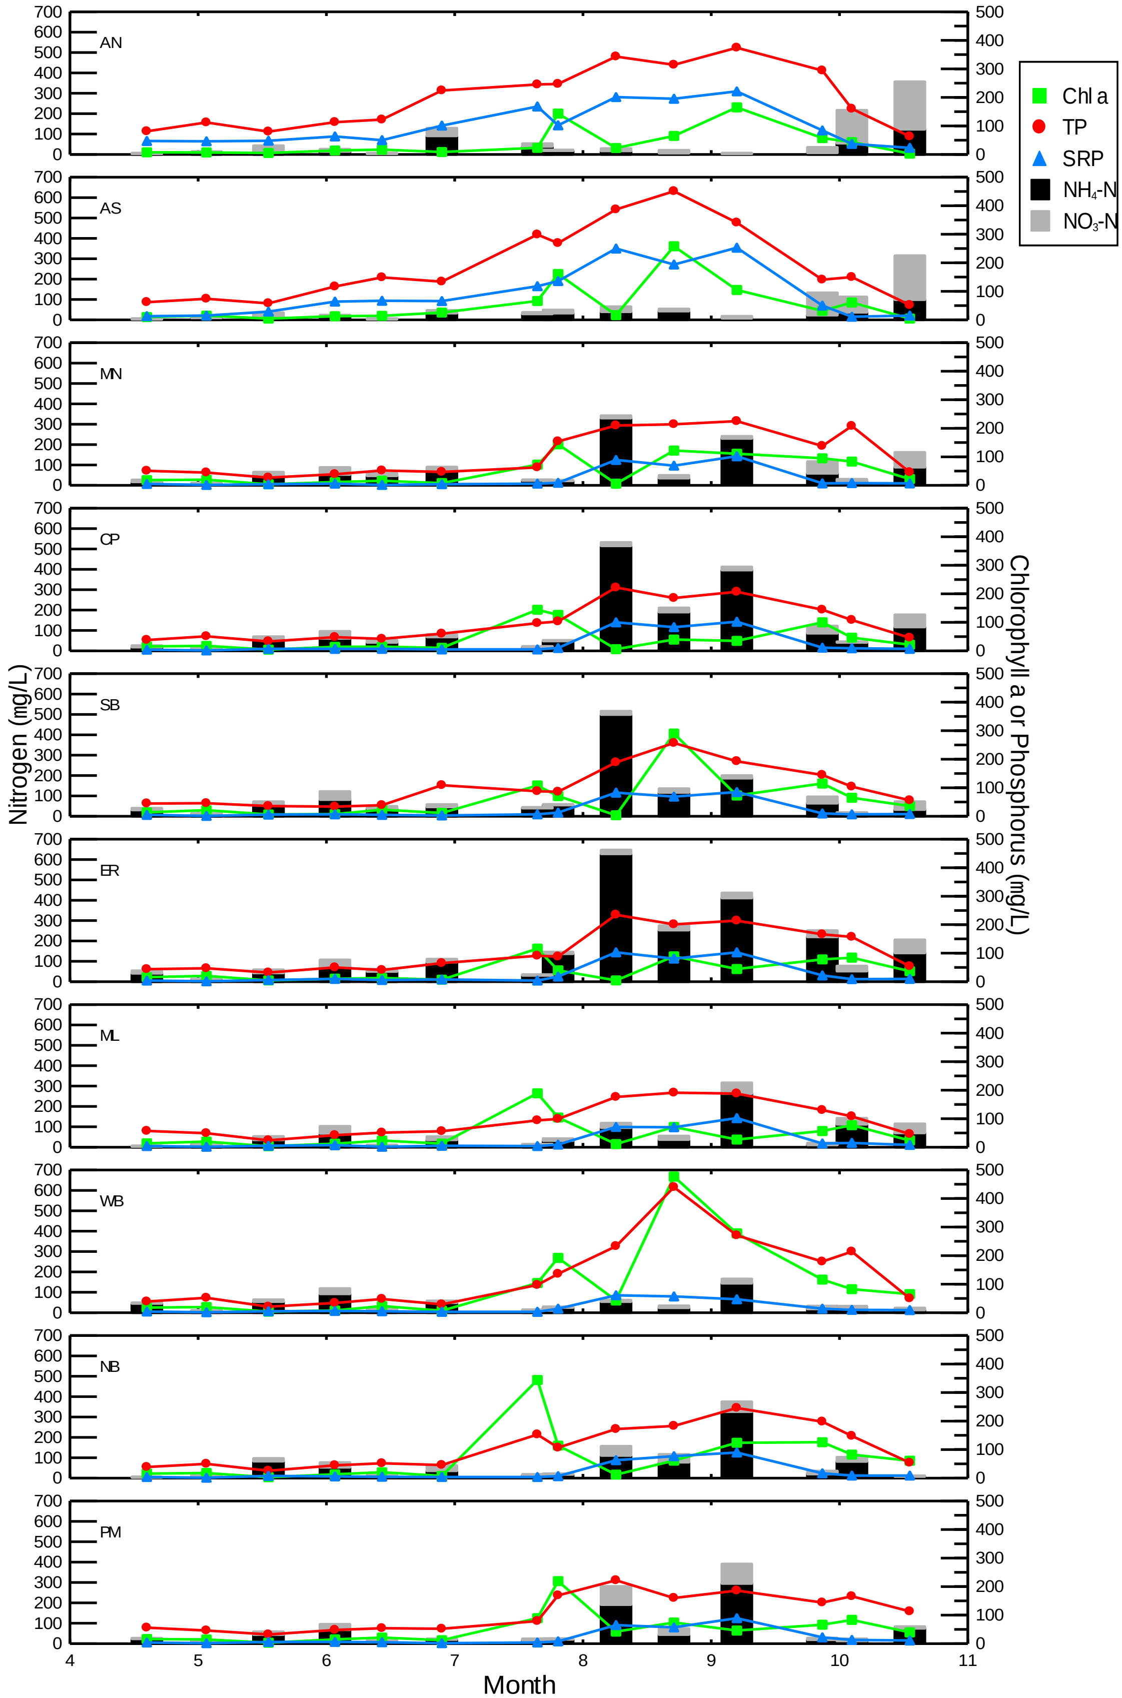

Figure 13. Chlorophyll, SRP, and TIN time-series for UKL and Agency Lake Stations, 2011.

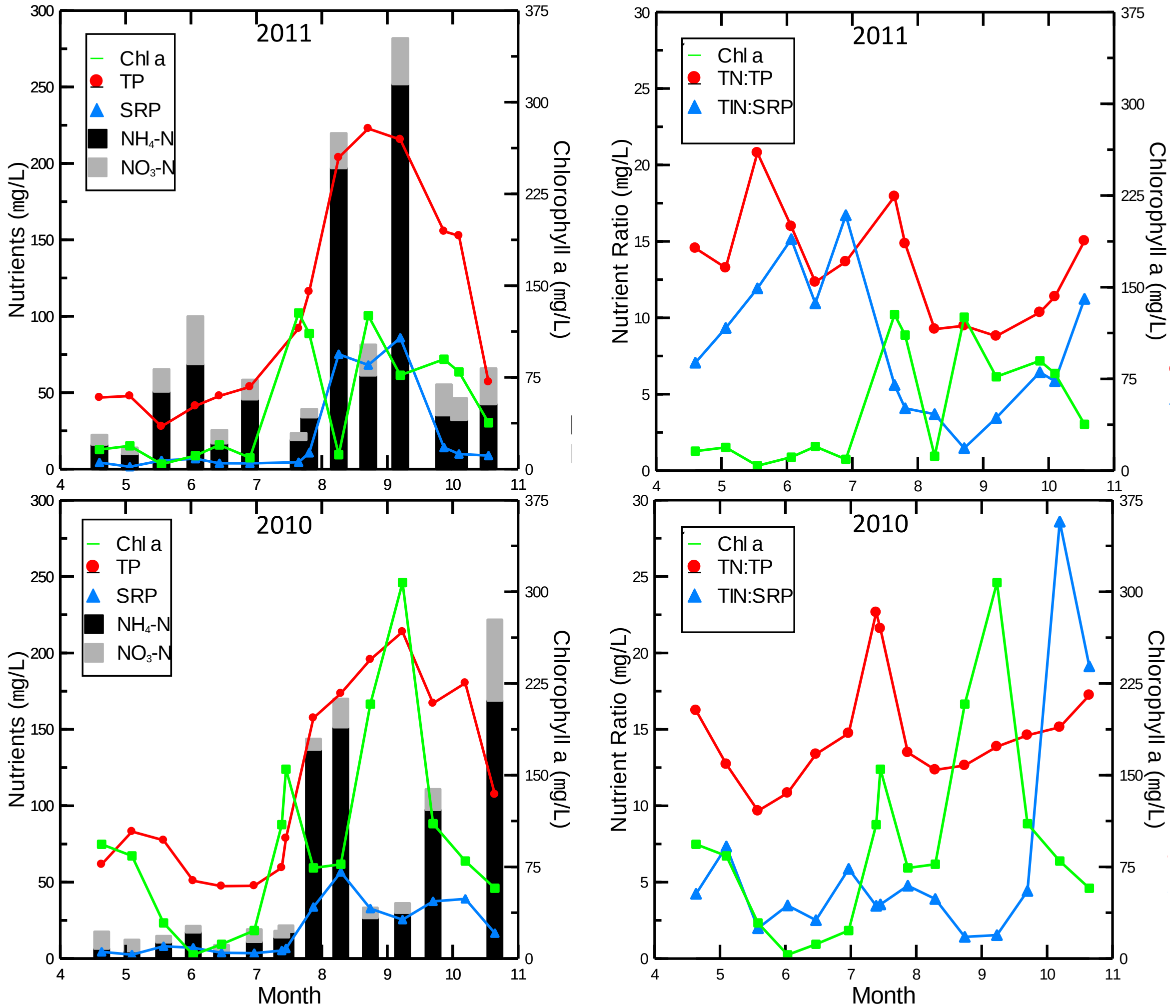

Figure 14. Lake-wide mean Chlorophyll, SRP, TIN, and nutrient ratio time-series for UKL Stations, 2010 and 2011.

In contrast to 2009 when chlorophyll to TP ratios greater than 1 (which indicate potential P limitation- see Kann 2010) were observed at a high frequency in June during the initial bloom, and to 2010 when CHL:TP ratios >1 occurred in April, part of May, July, and part of September (Kann 2011), CHL:TP ratios >1 occurred at a high frequency only in July of 2011 (Figure 15).

The underwater light environment is another factor that can influence both bloom dynamics and other water quality parameters, especially those that are photosynthetically driven. Although not discussed in detail here, a plot of photic zone depth (defined as the depth where 99% of incident light is absorbed as computed from extinction coefficients) relative to the maximum depth at UKL and Agency Lake stations shows that despite the shallow nature of the system that the photic zone depth was often shallower than maximum depth in 2011 (Figure 16; occurring when the blue line is above red line). The typical UKL pattern shows a relatively shallow photic zone during the spring diatom bloom, a deeper photic zone that extends the depth of the water column during much of May and early-June, a shallower photic zone during late-June to mid-July algal blooms, a decline (i.e., deeper photic zone- although not as extreme as the May decline) during

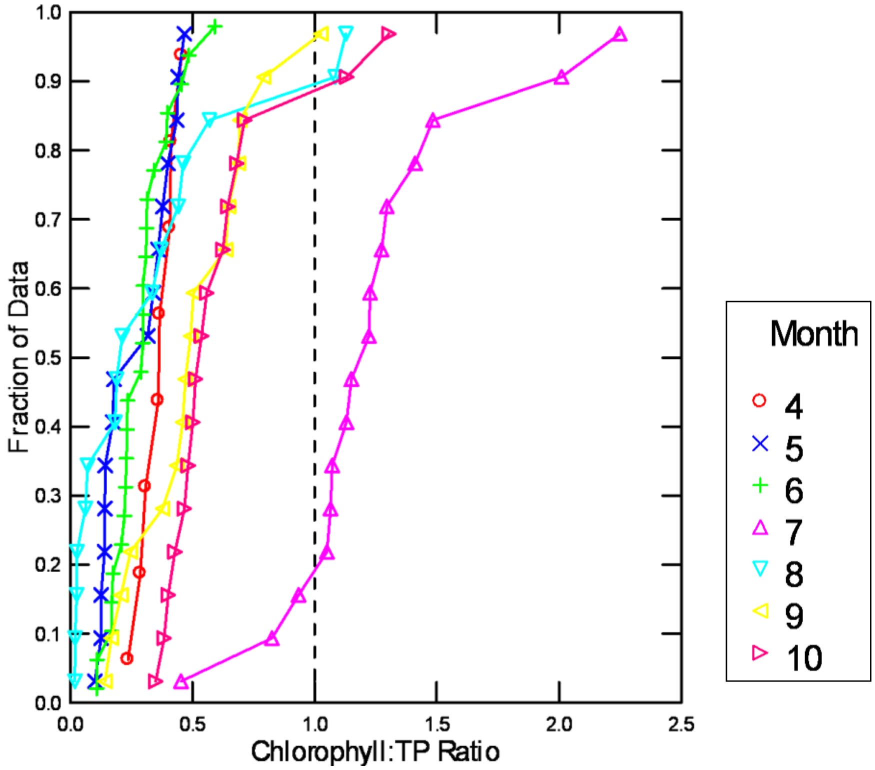

Figure 15. Quantile plot (cumulative frequency) of April-October chlorophyll to TP ratios in Upper Klamath Lake, 2011.

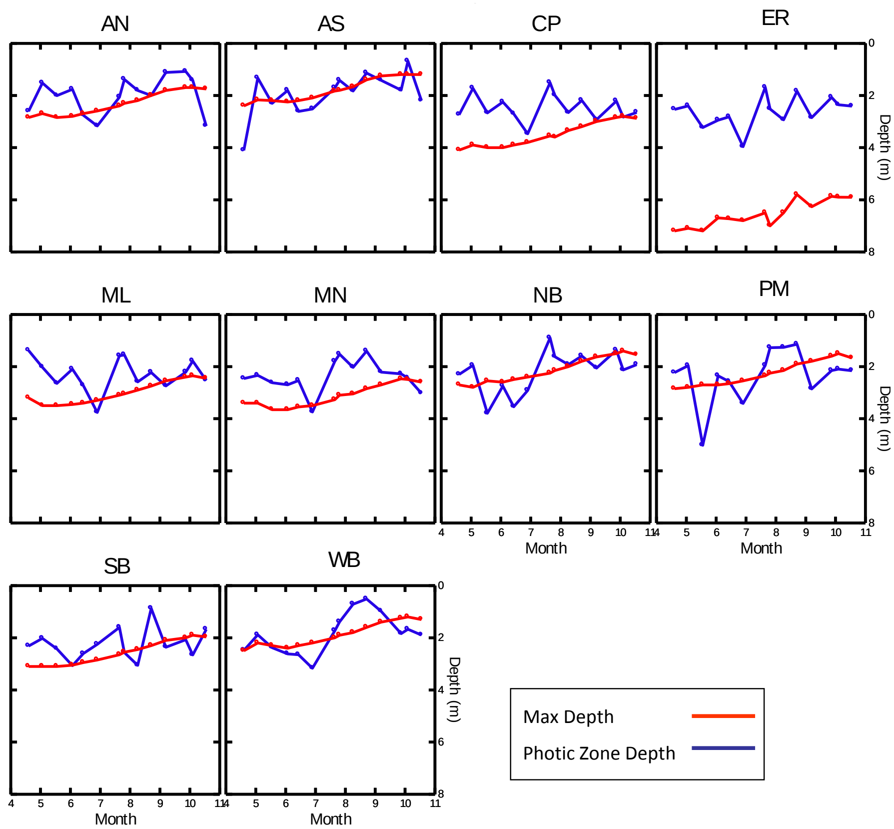

Figure 16. Photic zone depth and maximum depth at UKL and Agency Lake stations in 2011.

August bloom declines, and finally another shallow photic zone period during bloom rebound in late-August and September (Kann 2010; 2011). The 2011 pattern (Figure 16) was less pronounced than the typical pattern due to the overall bloom delay and lower biomass, but similar to other years, a percentage of the water column is outside of the photic zone (e.g., does not have sufficient light for photosynthesis; Figure 17). Light limitation is more apparent at the deeper ER station which showed a greater percentage of the water column to be light limited.

To the extent that underwater light is influenced by seasonal algal dynamics (in concert with ambient light and the interaction with lake depth), decreases in available light during the early spring of 2010 (as they were in 2009) were likely influenced by diatom blooms (Kann 2011). However, unlike 2009 when a "clear water" phase occurred in May as the diatoms declined, in 2010 the "clear water' phase did not occur until later in May and extended to the end of June. A decline in available light did not occur until mid-July of 2010 (this occurred during June of 2009) as the *Aphanizomenon* bloom increased (Figure 17). In contrast, in 2011 there was no apparent "clear water" phase until late-June, after which the algal bloom increased and water transparency declined (Figure 17).

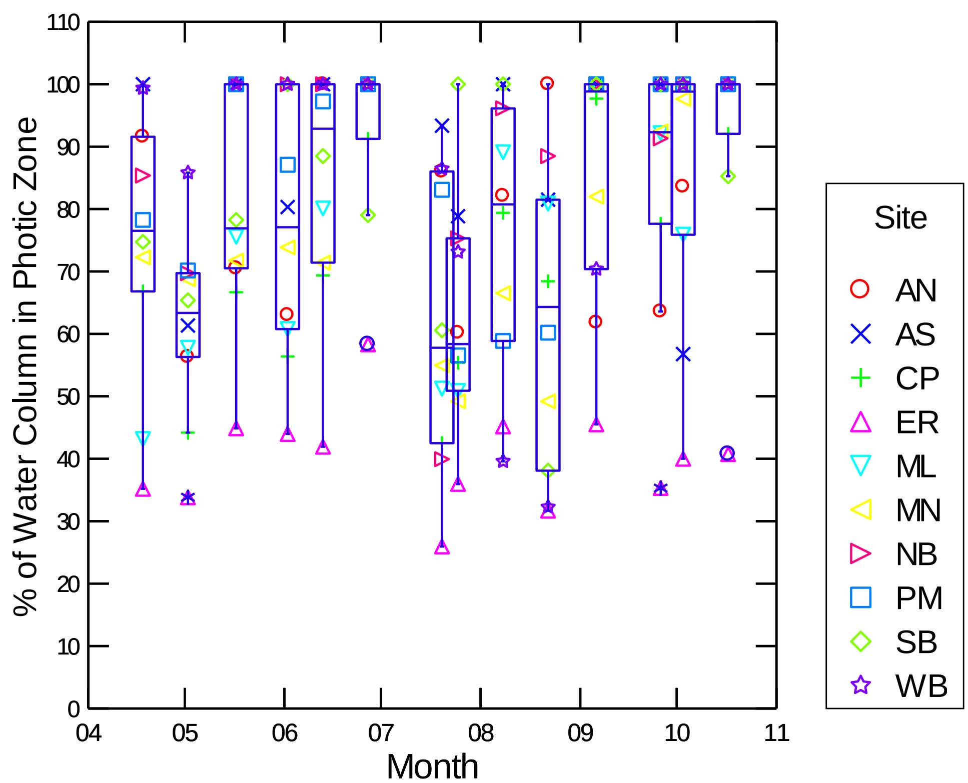

Figure 17. Percent of the water column in the photic zone for UKL and Agency Lake Stations, 2011.

Clearly, as is typical for many shallow lake ecosystems, the concentration of nutrients, their ratios, the underwater light climate, and climatic variables (e.g., temperature and wind speed) are important determinants of annual bloom dynamics of *Aphanizomenon* in UKL. During the 2010 and 2009 growing seasons (see Kann 2010; 2011) it appears that the late-spring decline in TN:TP (indicating more nitrogen limiting conditions), a later (June as opposed to May) "clear water" phase (nitrogen fixation generally has a high energy/light requirement) and cooler May-June temperatures were important determinants of *Aphanizomenon* bloom timing. Likewise, relatively high TIN concentrations and high TIN:SRP ratios, a late "clear water" phase, generally cooler and windier conditions during late-May and early-June, and cool temperatures in July apparently influenced bloom dynamics in 2011. The interaction of these variables as well as other controlling factors such as lake level and hydrodynamic patterns could be explored with additional multivariate statistical analyses on the entire dataset.

Comparison of 2011 to Previous 1990-2010 Data

To facilitate inter-annual comparisons of the major water quality variables, lake-wide means were computed for UKL-only and Agency Lake-only. The distributions for the June-September period are shown in Figures 18-21 and summary statistics in Tables 3 and 4. Similar to 2010, the June-Sep UKL-only pH distribution for 2011 was among the lowest for the period of record, and DO among the highest (Figure 18; Table 3). pH was especially low, showing the lowest

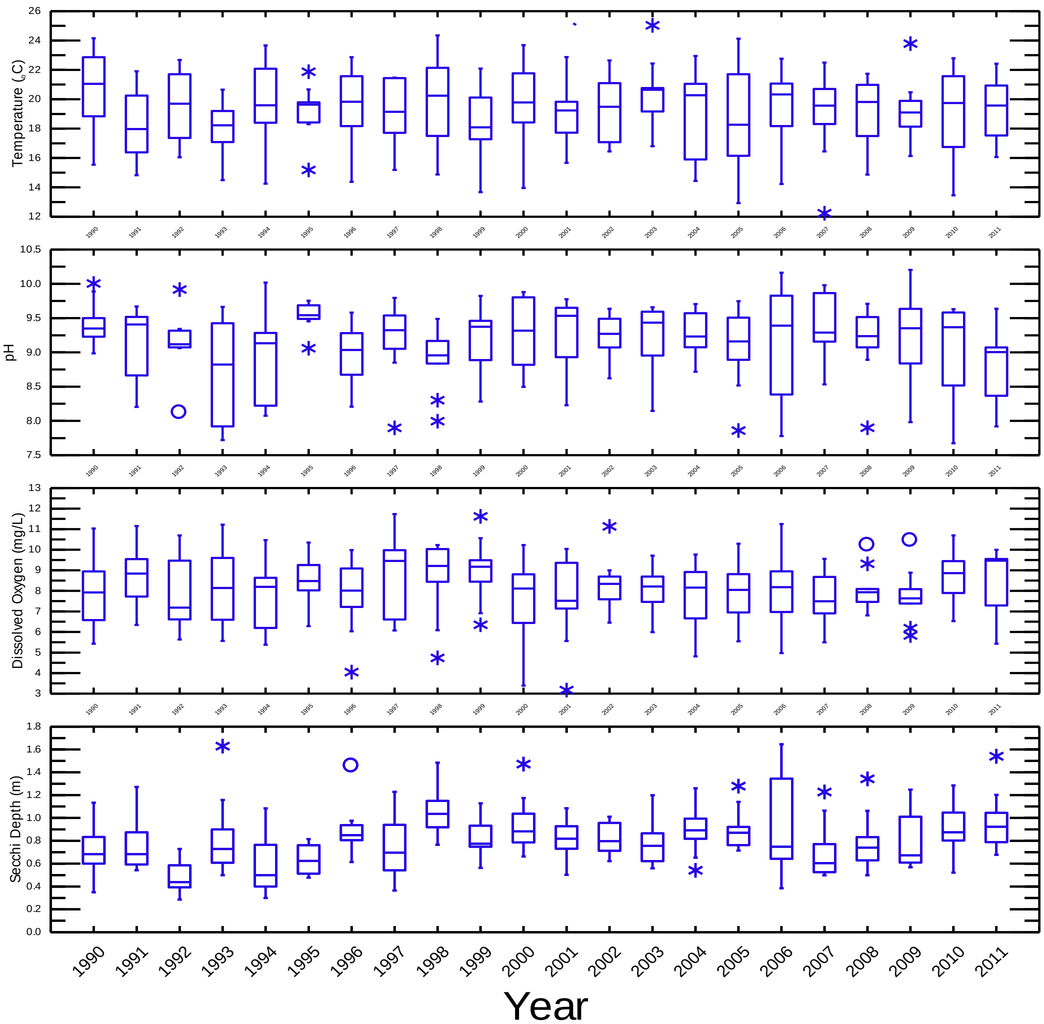

Figure 18. June-September distribution of UKL-only lake-wide means for T (˚C), pH, D.O (mg/L), and Secchi depth, 1990-2011.

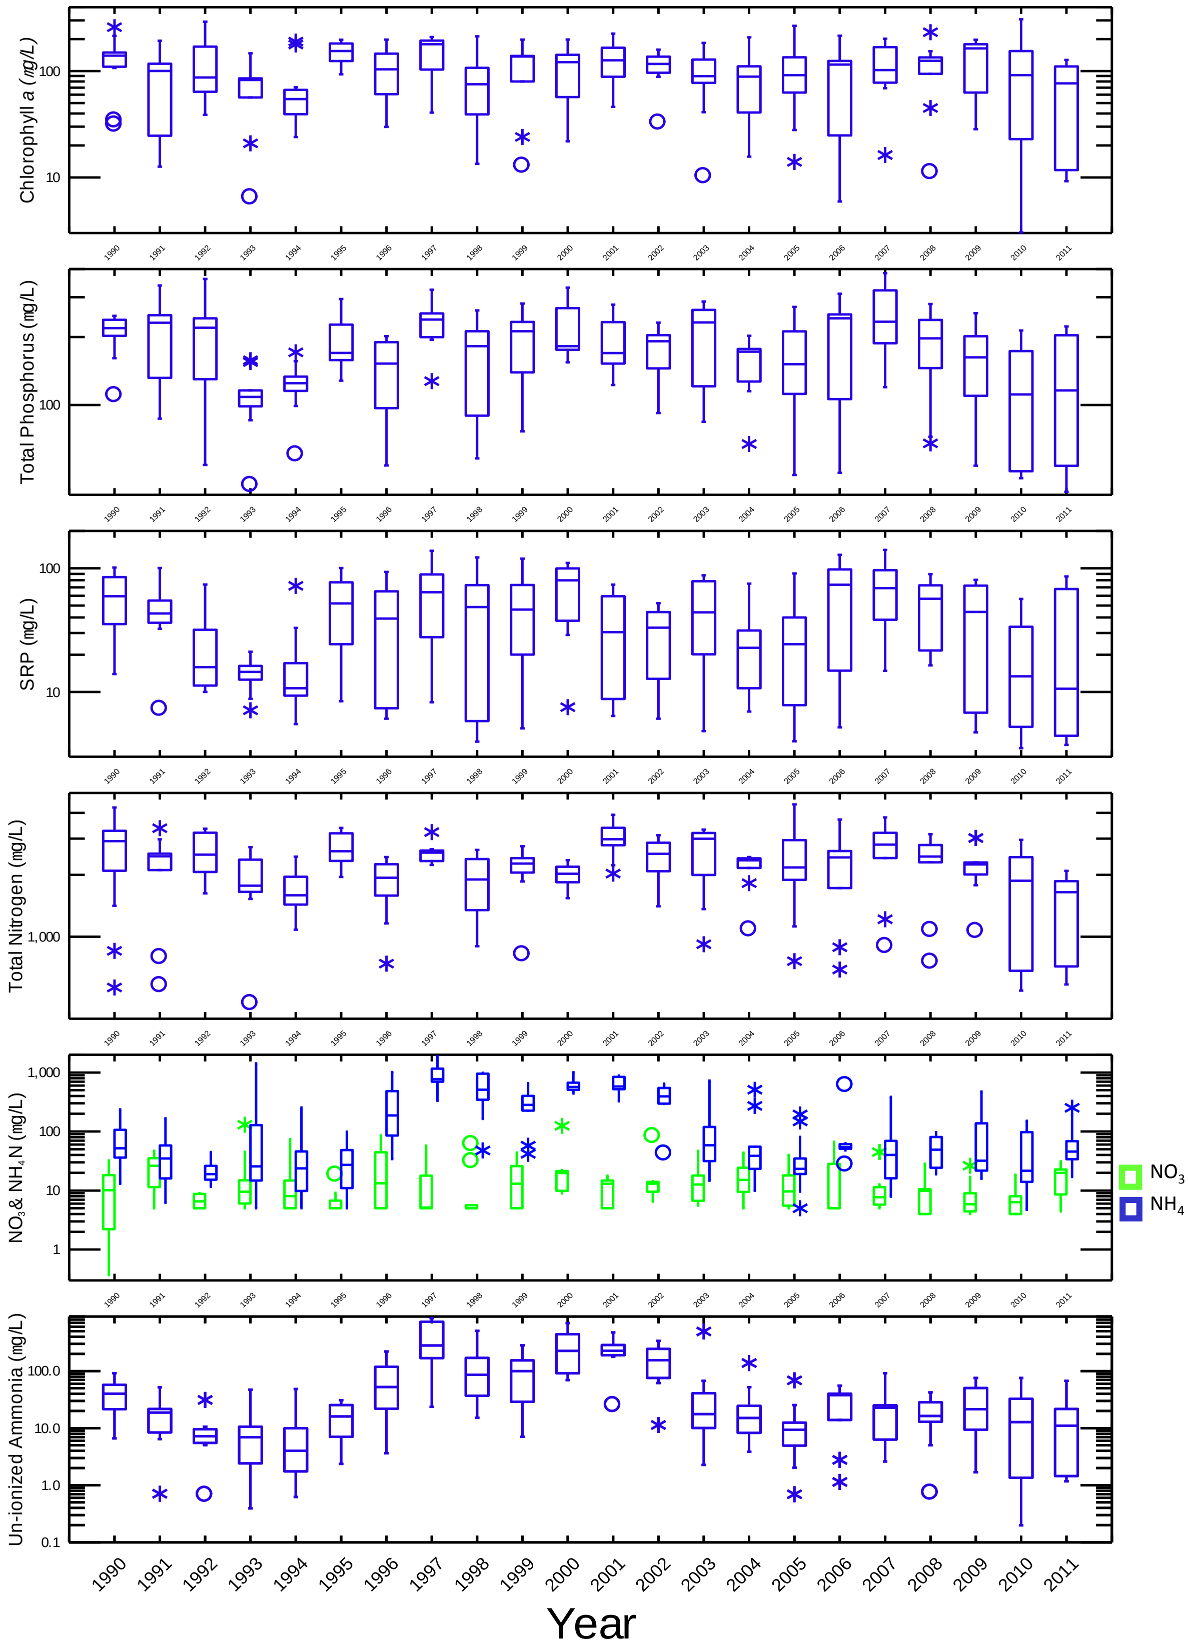

Figure 19. June-September distribution of UKL-only lake-wide means for CHL, TP, SRP, TN, NO_3+ NO_2-N and NH_4-N, 1990-2011.

inter-quartile range for the period of record. The 2011 median DO concentration was higher than all other years for the period of record. As expected due to its controlling effect on pH, median CHL in 2011 tended to be among the lowest for the period of record, and the lower quartile value was the lowest of the 22 year period. Although 2010 was also low (Kann 2011), overall values were noticeably lower than 2010 (Figure 19). A similar pattern was shown for 2011 TP, SRP, and TN which were also among the lowest of the period of record, but were also similar to 2010 (Figure 19). For the 22 years of record, the ammonia distribution was similar from 1990-1995, was elevated from 1996-2002, and then decreased to pre-1996 levels during the past 9 years (2003-2011). However, both 2009 and 2010 showed somewhat higher ammonia concentrations than the previous 5 years, and the lower-quartile was higher in 2011 than the previous 4 years (Figure 19).

For Agency Lake, DO was also noticeably higher in 2011 and 2010 than most previous years, and while pH was also lower in 2011 than many other years, the effect was not as strong as it was for UKL (Figure 20; Table 4). Lower quartile values of CHL, TP, SRP, and TN in Agency

Lake were not as obviously low as was UKL or as occurred in 2010 (Figure 21; Table 4). In addition, the NO_3-NO_2-N distribution was among the lowest for the period of record, and NH_4-N tended to follow the overall 22 year cyclical pattern described above (Figure 21). Both Agency and UKL Lakes continued to show several periods of apparent cyclical increase and decrease for both TP and SRP over the period of record (Figure 19 and Figure 21).

SUMMARY

With the addition of 2011 data, the UKL water quality/limnological database now includes 22 years of data and includes the years 1990-2011. Given the dynamic and variable nature of shallow, high productivity lakes such as UKL, a long-term monitoring program is essential for assessing change relative to management programs, as well as for understanding lake dynamics.

For example, as noted in earlier reports, ongoing wetland restoration is occurring in vast areas of the periphery of UKL, riparian and nutrient management plans (e.g., Oregon 1010 and TMDL plans) have been developed, and water use plans have been implemented (e.g., KBRT Wood River Valley programs).

Continued monitoring is recommended to accommodate the restoration time-frame (restoration of ecological function can be a multi-decade process) for Klamath Basin activities and to increase statistical power (sample size) for multi-variable analyses. Such a long-term database allows for statistical time series or trend analysis, as well as multi-variable assessment of the relationship between controlling variables (e.g., climate) and important water quality parameters (e.g., see Jassby and Kann 2010).

Further analysis (beyond the scope of the current summary report) of the noticeable difference in CHL, as well as other water quality parameters between 2009, 2010, and 2011 may provide an opportunity to gain further insight into annual controlling factors of bloom dynamics. Additional time-series and trend analyses such as Seasonal Kendal Tests are recommended, as well as integration with current lake literature on shallow lakes and *Aphanizomenon* bloom dynamics.

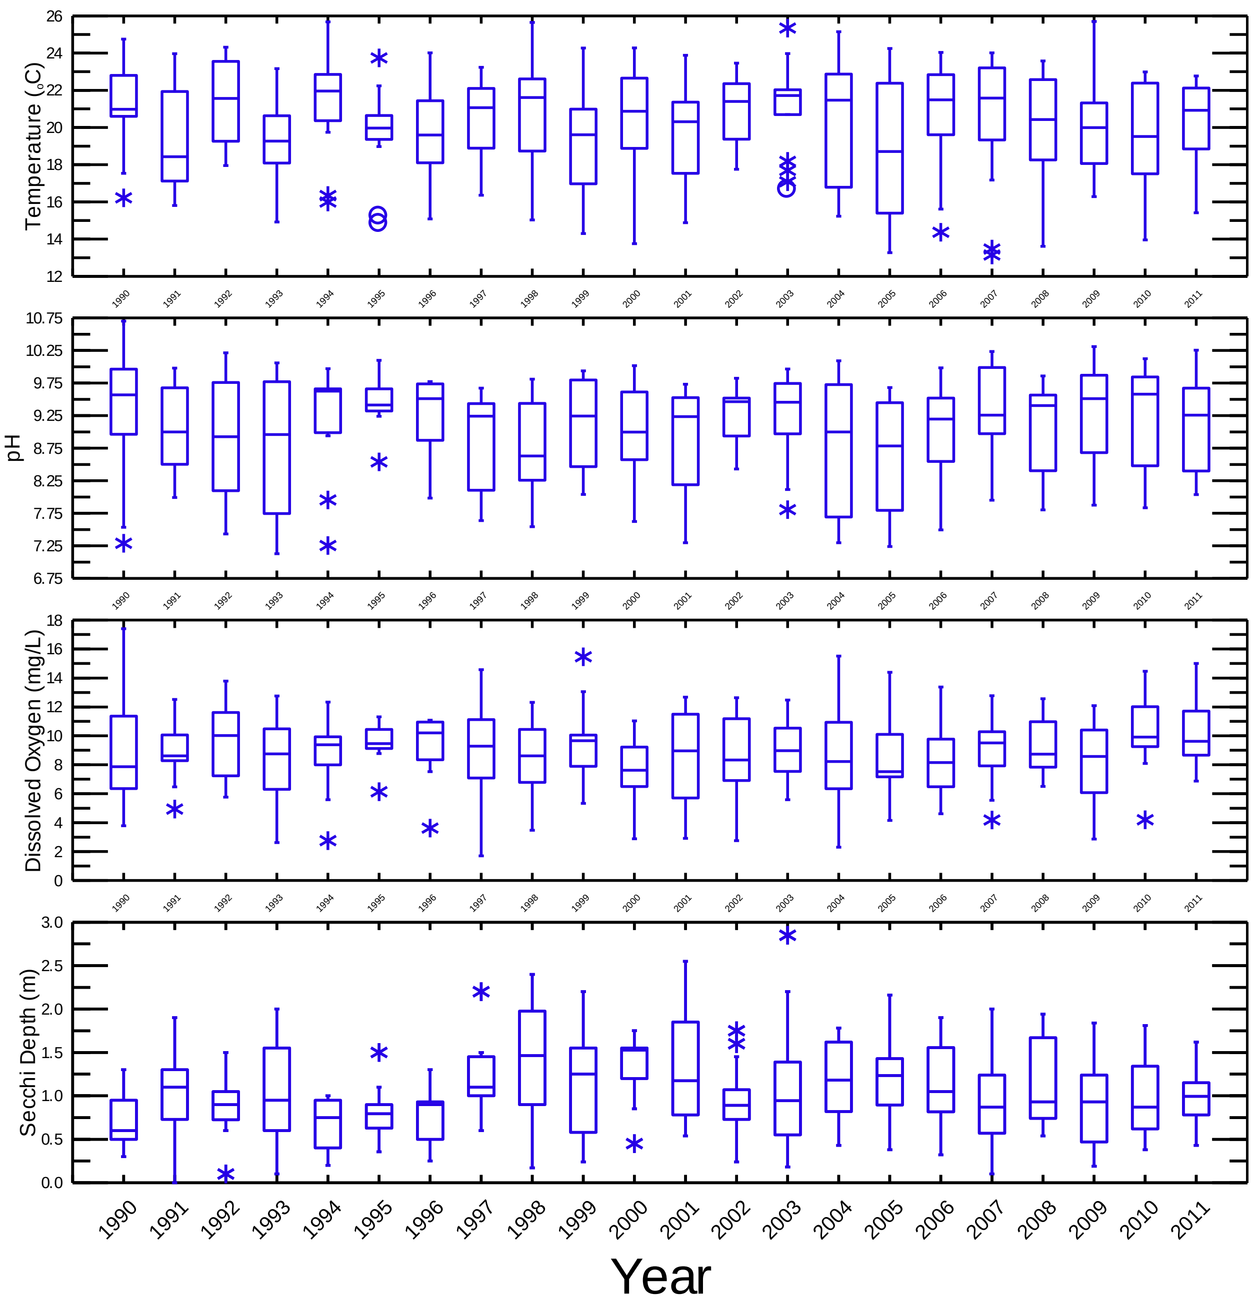

Figure 20. June-September distribution of Agency Lake means for T (˚C), pH, D.O (mg/L), and Secchi depth, 1990-2011.

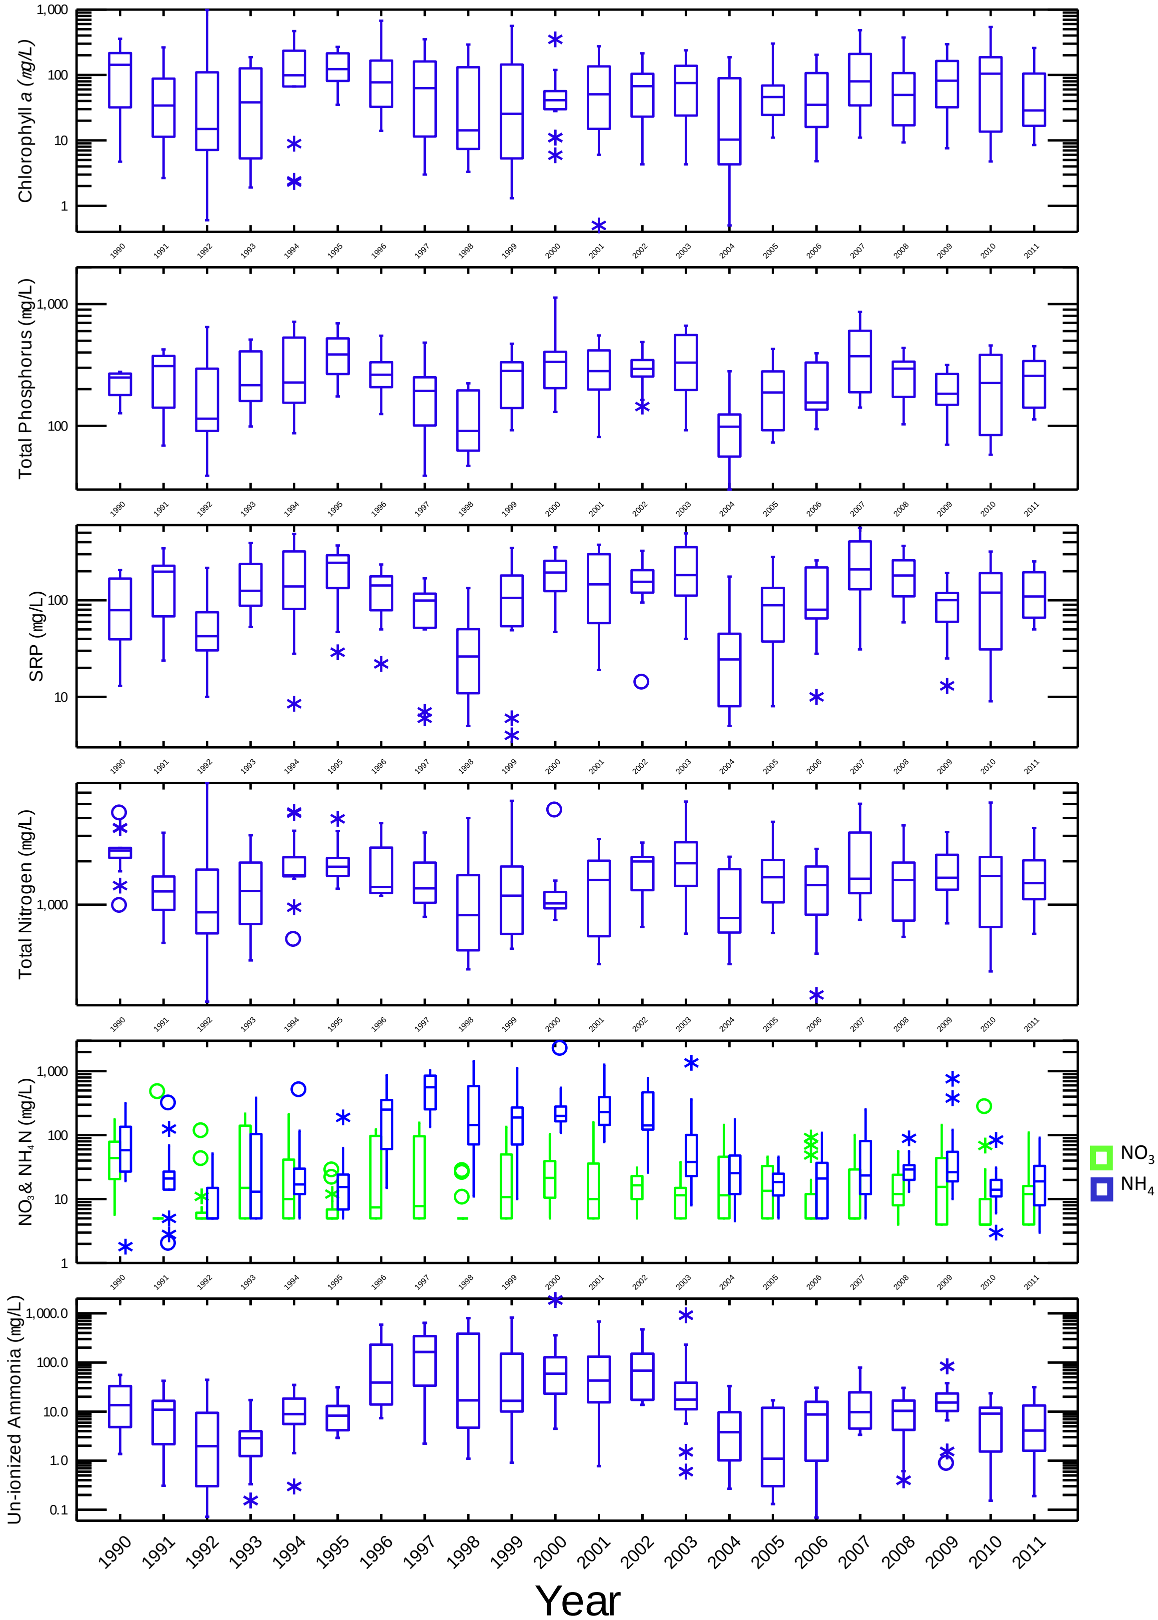

Figure 21. June-September distribution of Agency Lake means for CHL, TP, SRP, TN, NO_3+ NO_2-N, and NH_4-N, 1990-2011.

Table 4. Summary statistics for June-September Agency Lake means, 1990-2011 (LQ=Lower Quartile; UQ=Upper Quartile).

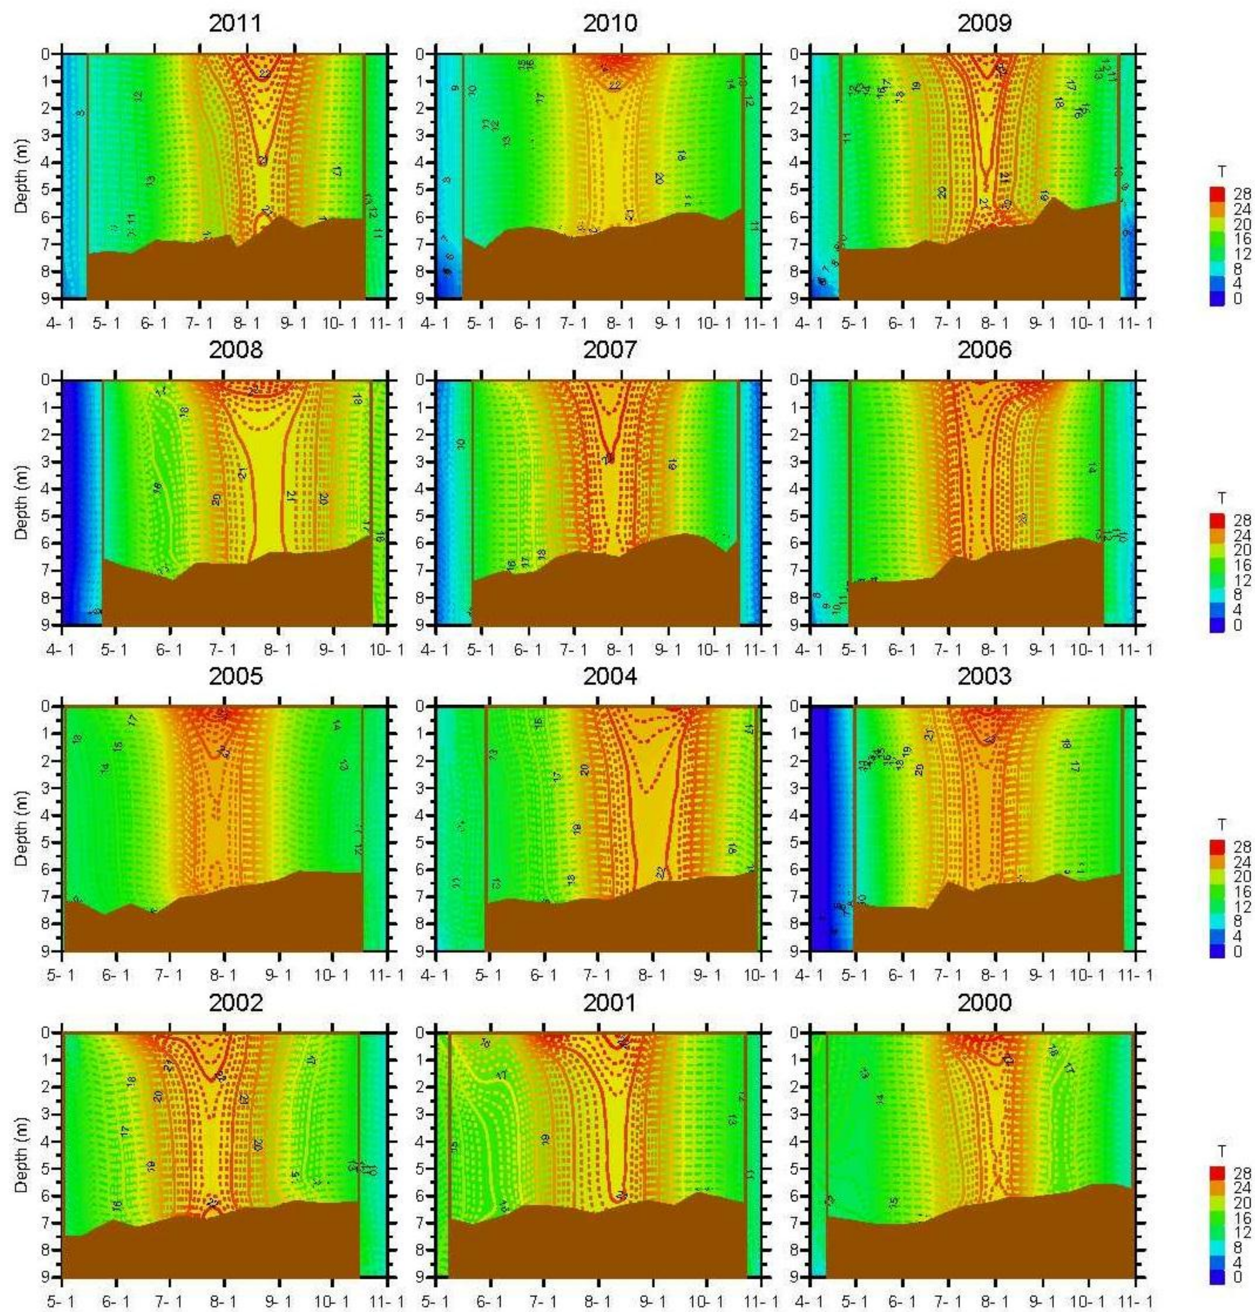
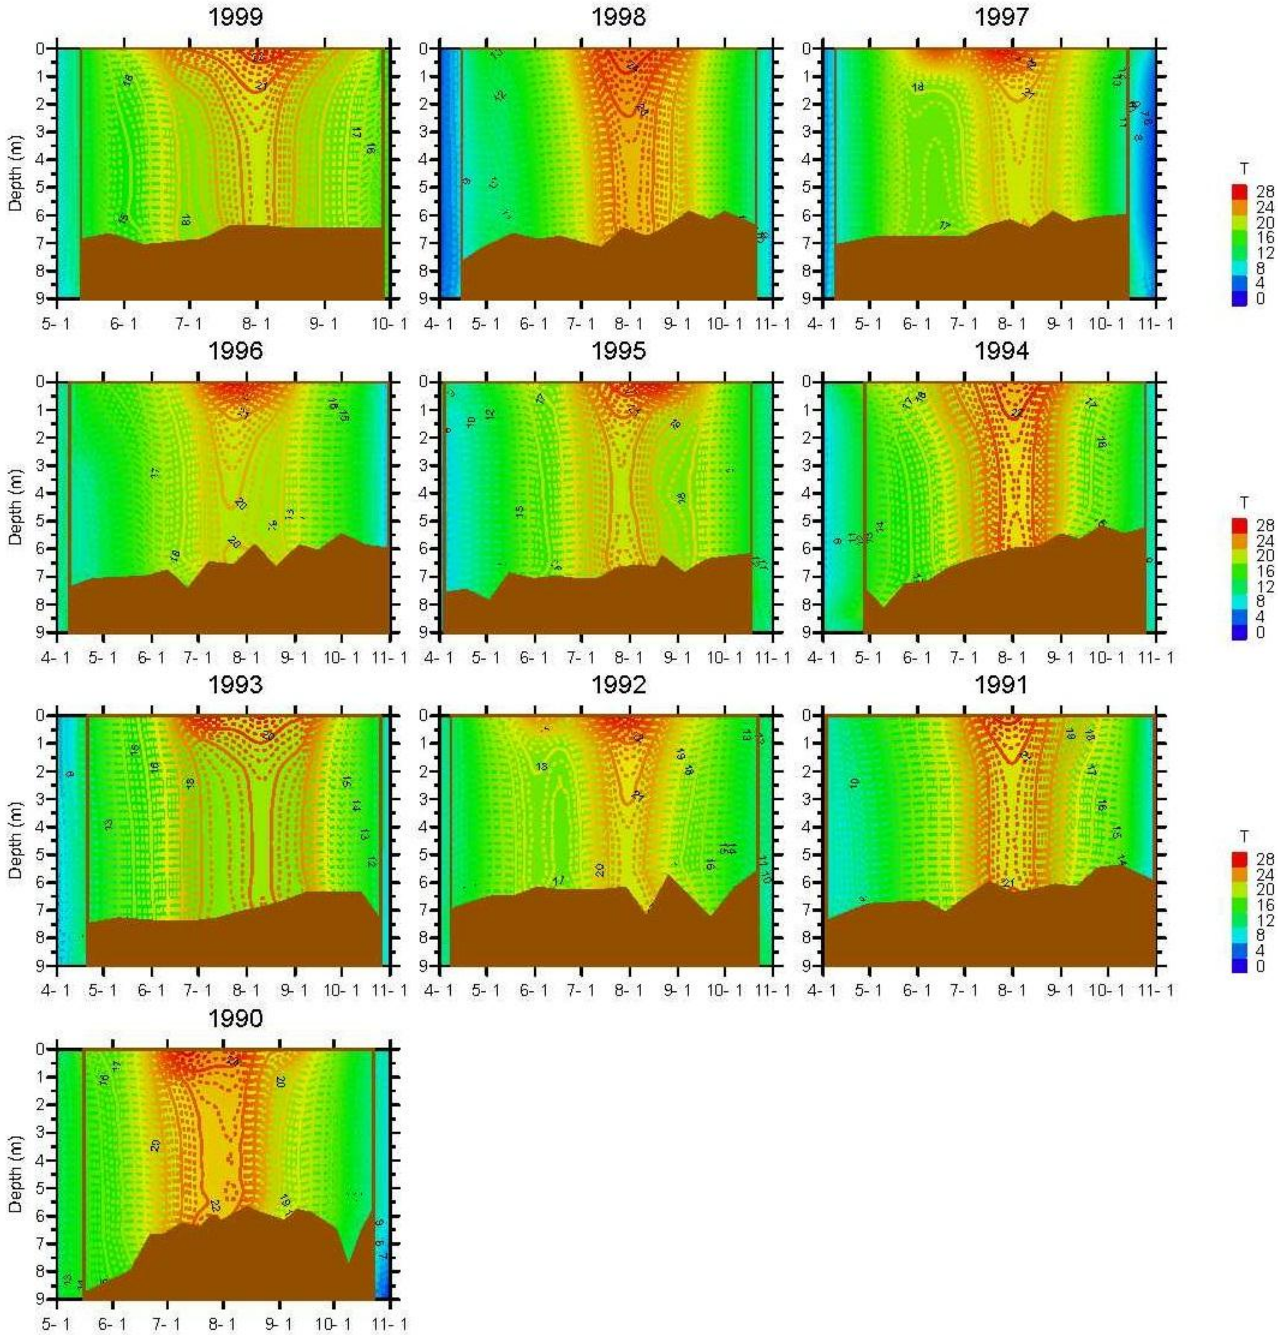
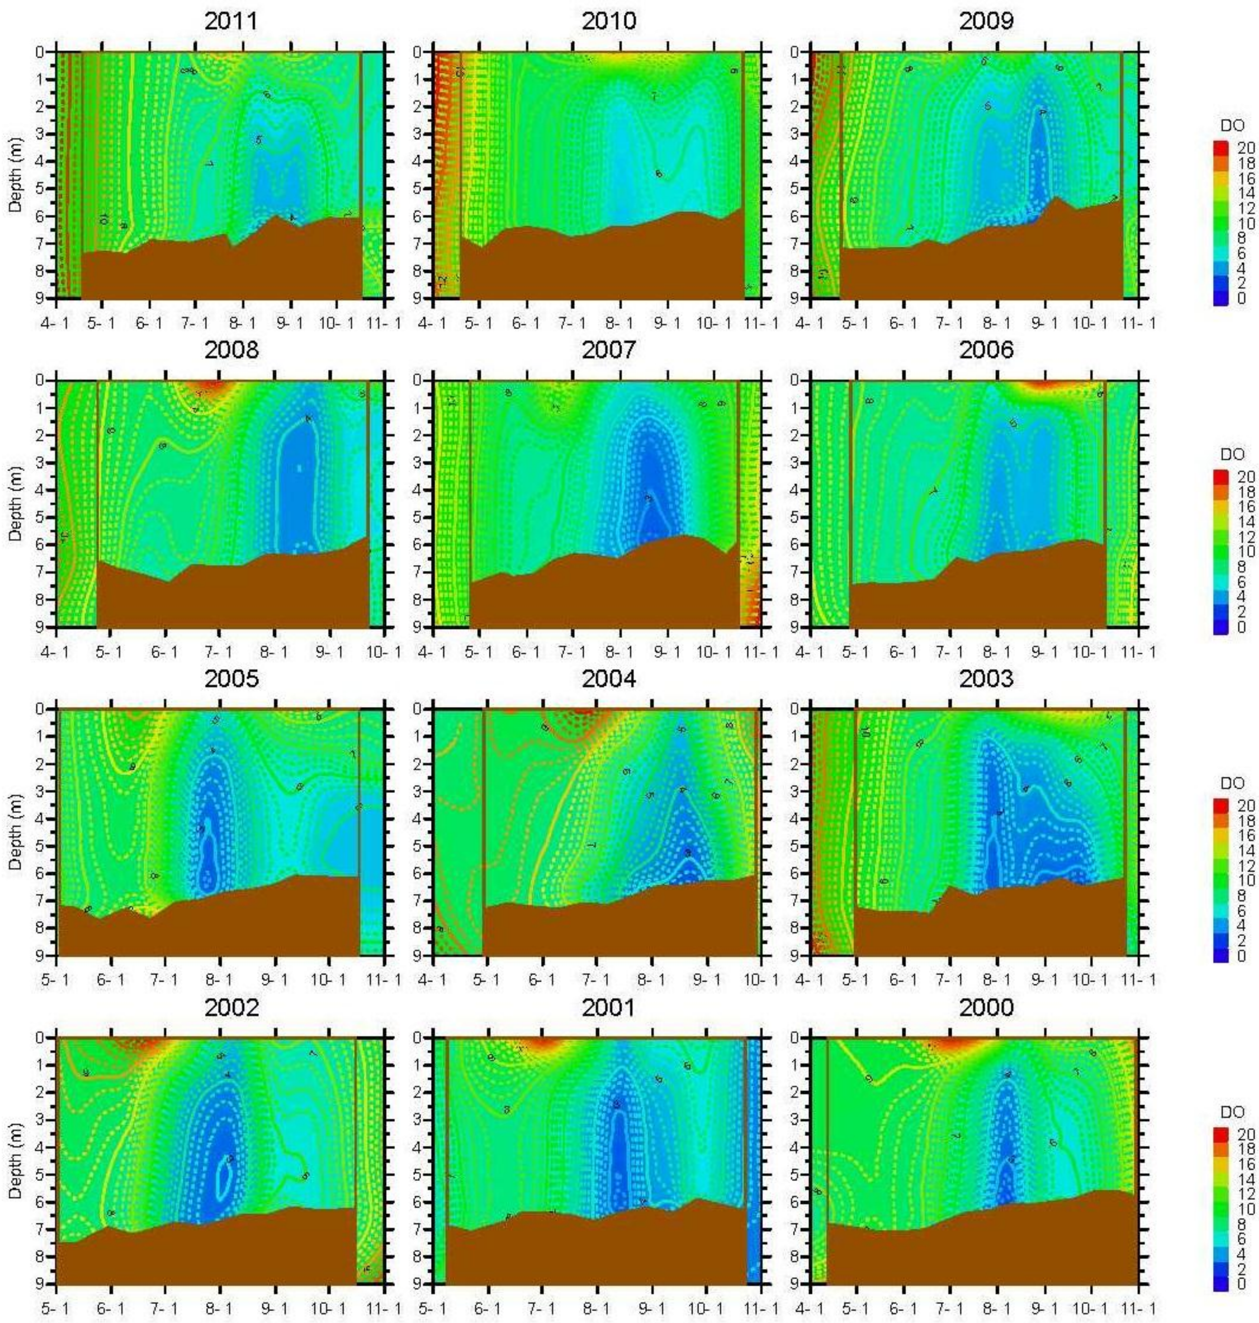
APPENDIX I: Seasonal and water column trends in water quality profile data (T, DO, and pH)



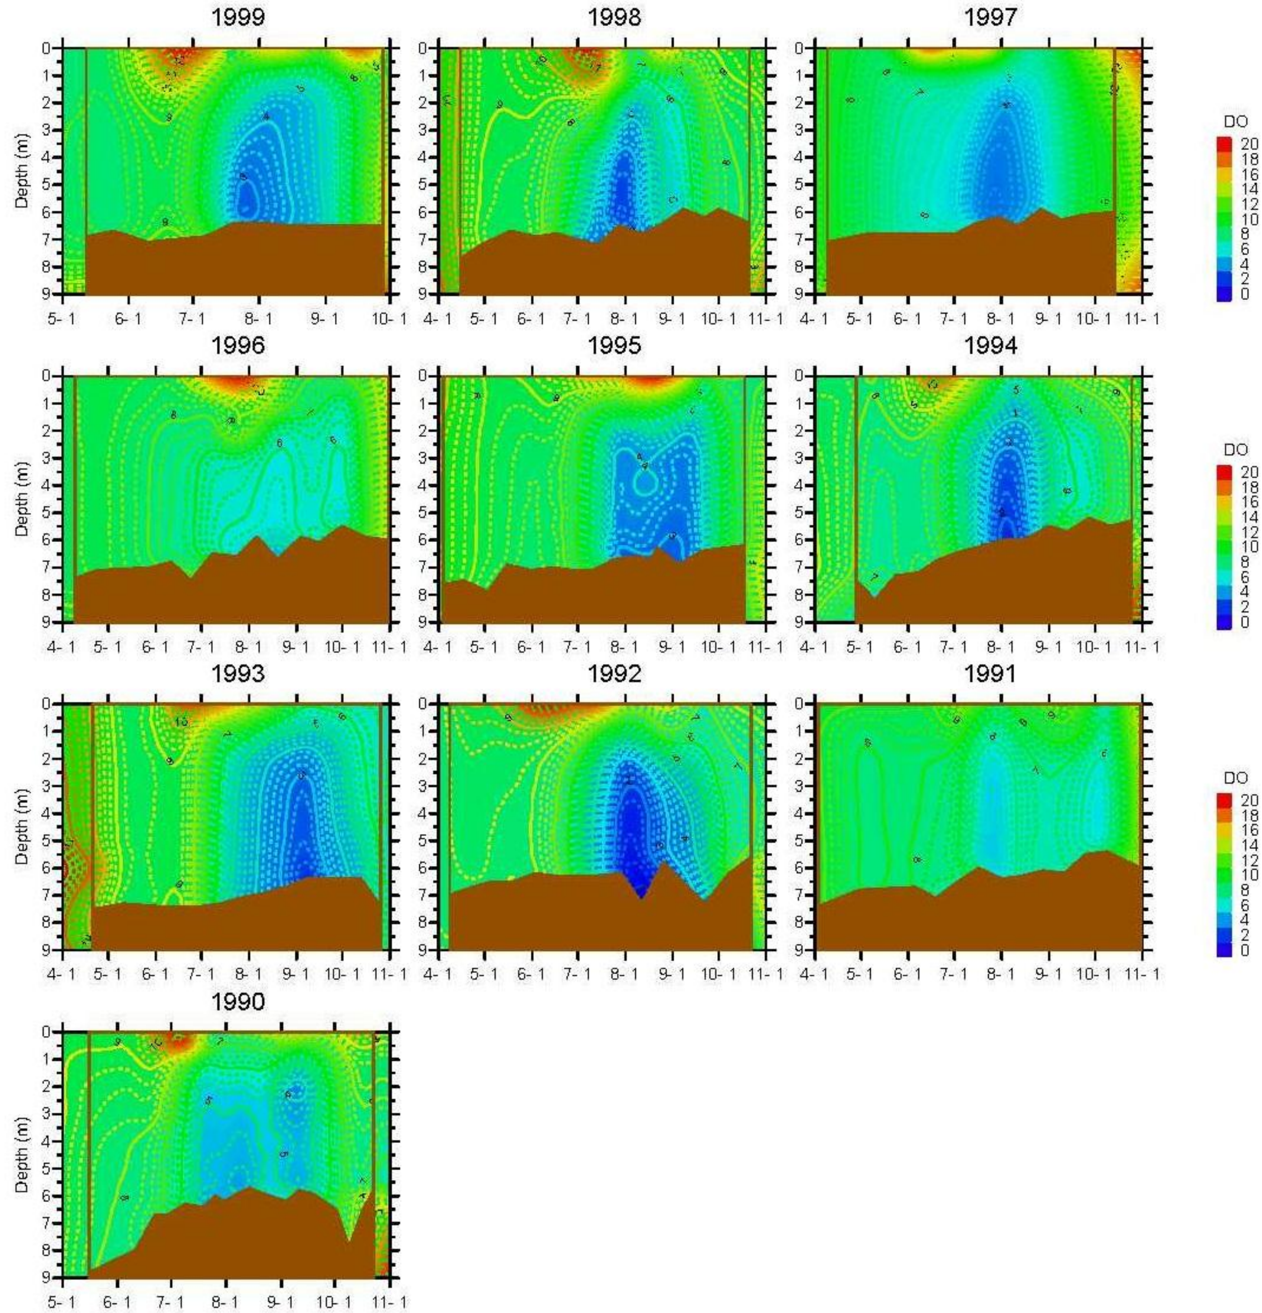
Depth-time distributions of isotherms of temperature (˚C) at UKL station Eagle Ridge (ER), 2000-2011. Note: 1) brown shaded area on the abscissa denotes the bottom profile depth, and 2) contours are not valid outside of vertical brown lines (begin and end dates for seasonal sampling).



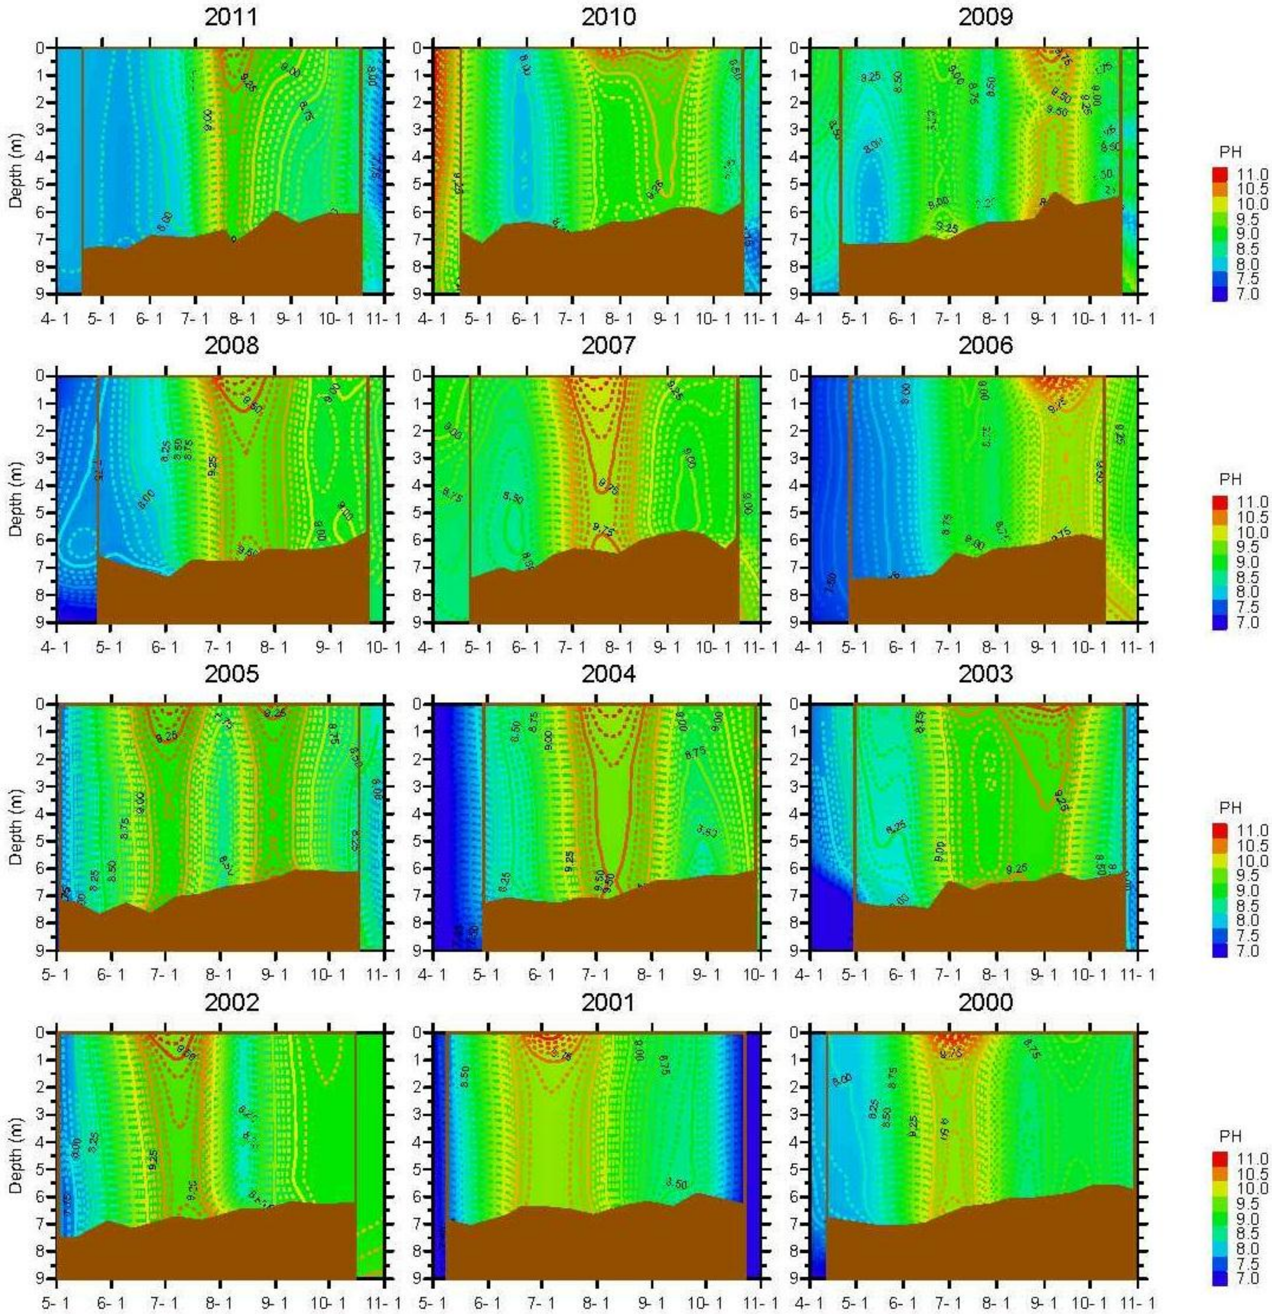
Depth-time distributions of isotherms of temperature (˚C) at UKL station Eagle Ridge (ER), 1990-1999. Note: 1) brown shaded area on the abscissa denotes the bottom profile depth, and 2) contours are not valid outside of vertical brown lines (begin and end dates for seasonal sampling).



Depth-time distributions of isopleths of dissolved oxygen (mg/L) at UKL station Eagle Ridge (ER), 2000-2011. Note: 1) brown shaded area on the abscissa denotes the bottom profile depth, and 2) contours are not valid outside of vertical brown lines (begin and end dates for seasonal sampling).

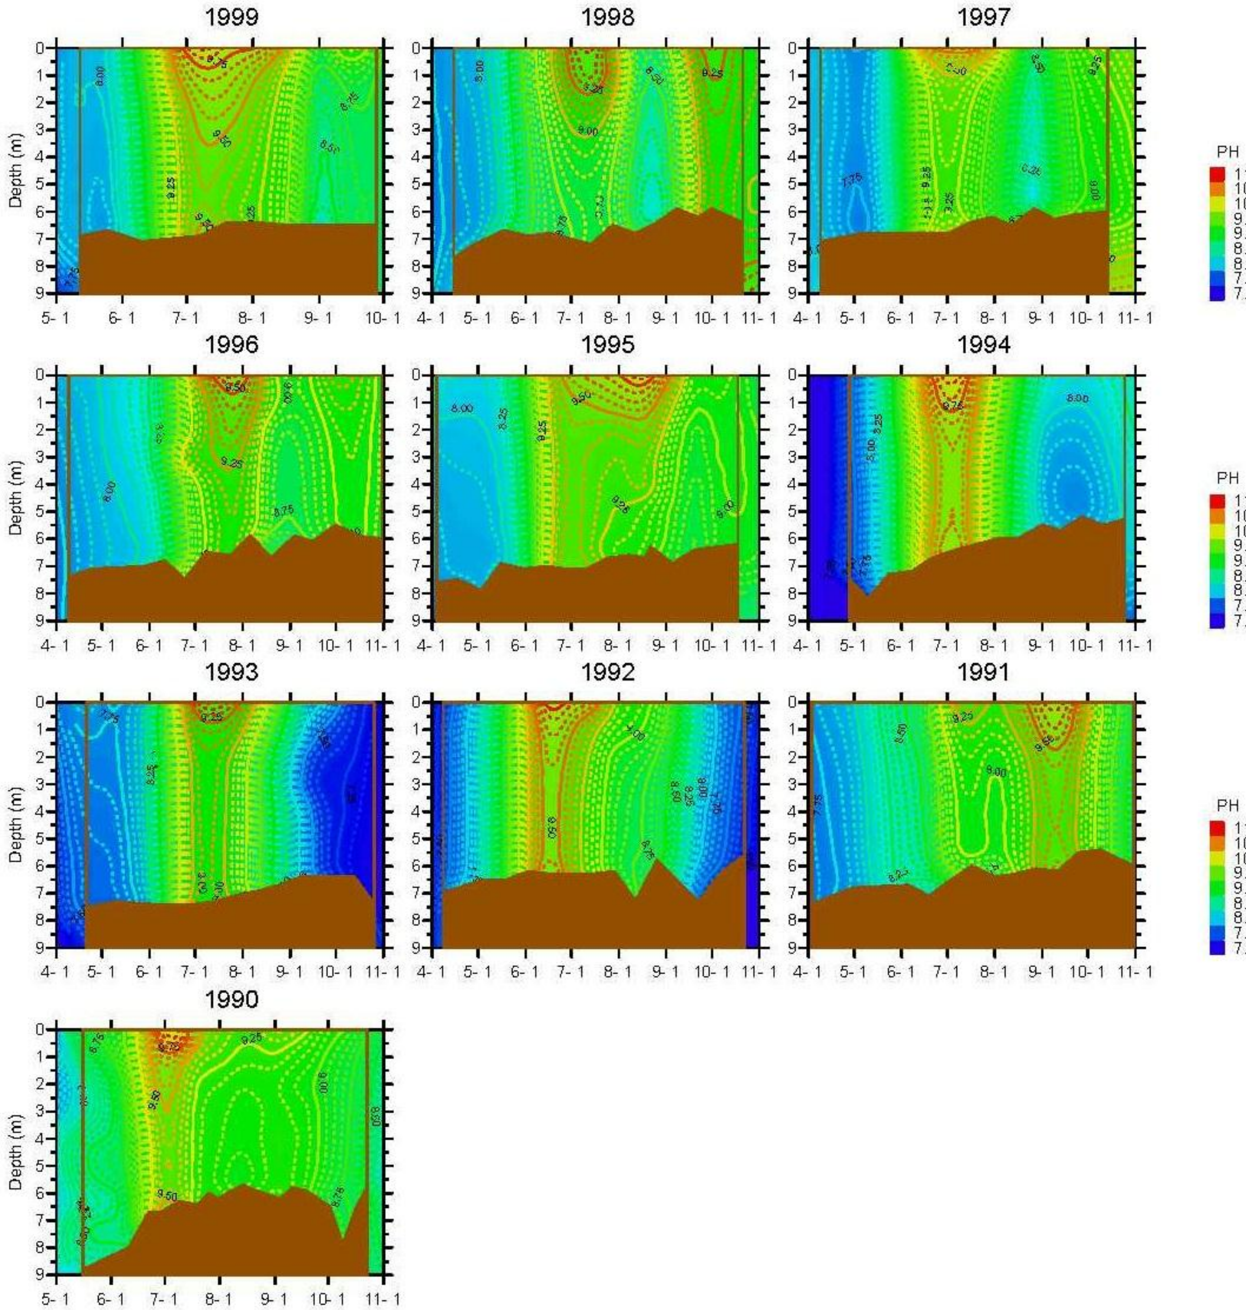


Depth-time distributions of isopleths of dissolved oxygen (mg/L) at UKL station Eagle Ridge (ER), 1990-1999. Note: 1) brown shaded area on the abscissa denotes the bottom profile depth, and 2) contours are not valid outside of vertical brown lines (begin and end dates for seasonal sampling).

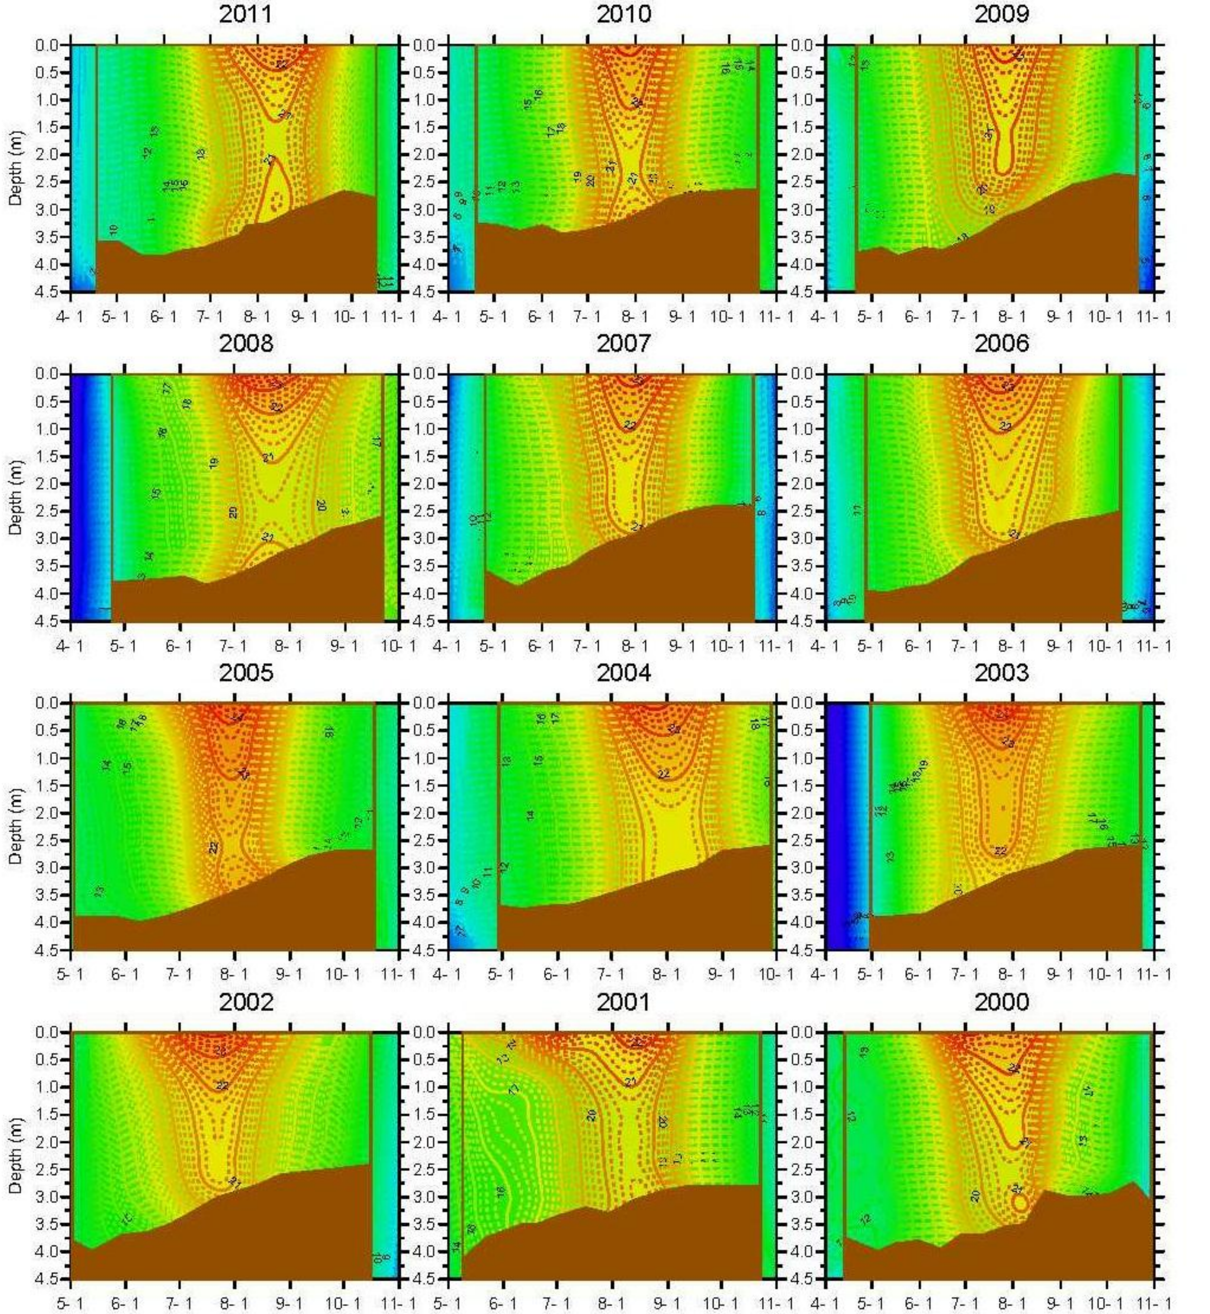


Depth-time distributions of isopleths of pH at UKL station Eagle Ridge (ER), 2000-2011. Note: 1) brown shaded area on the abscissa denotes the bottom profile depth, and 2) contours are not valid outside of vertical brown lines (begin and end dates for seasonal sampling).

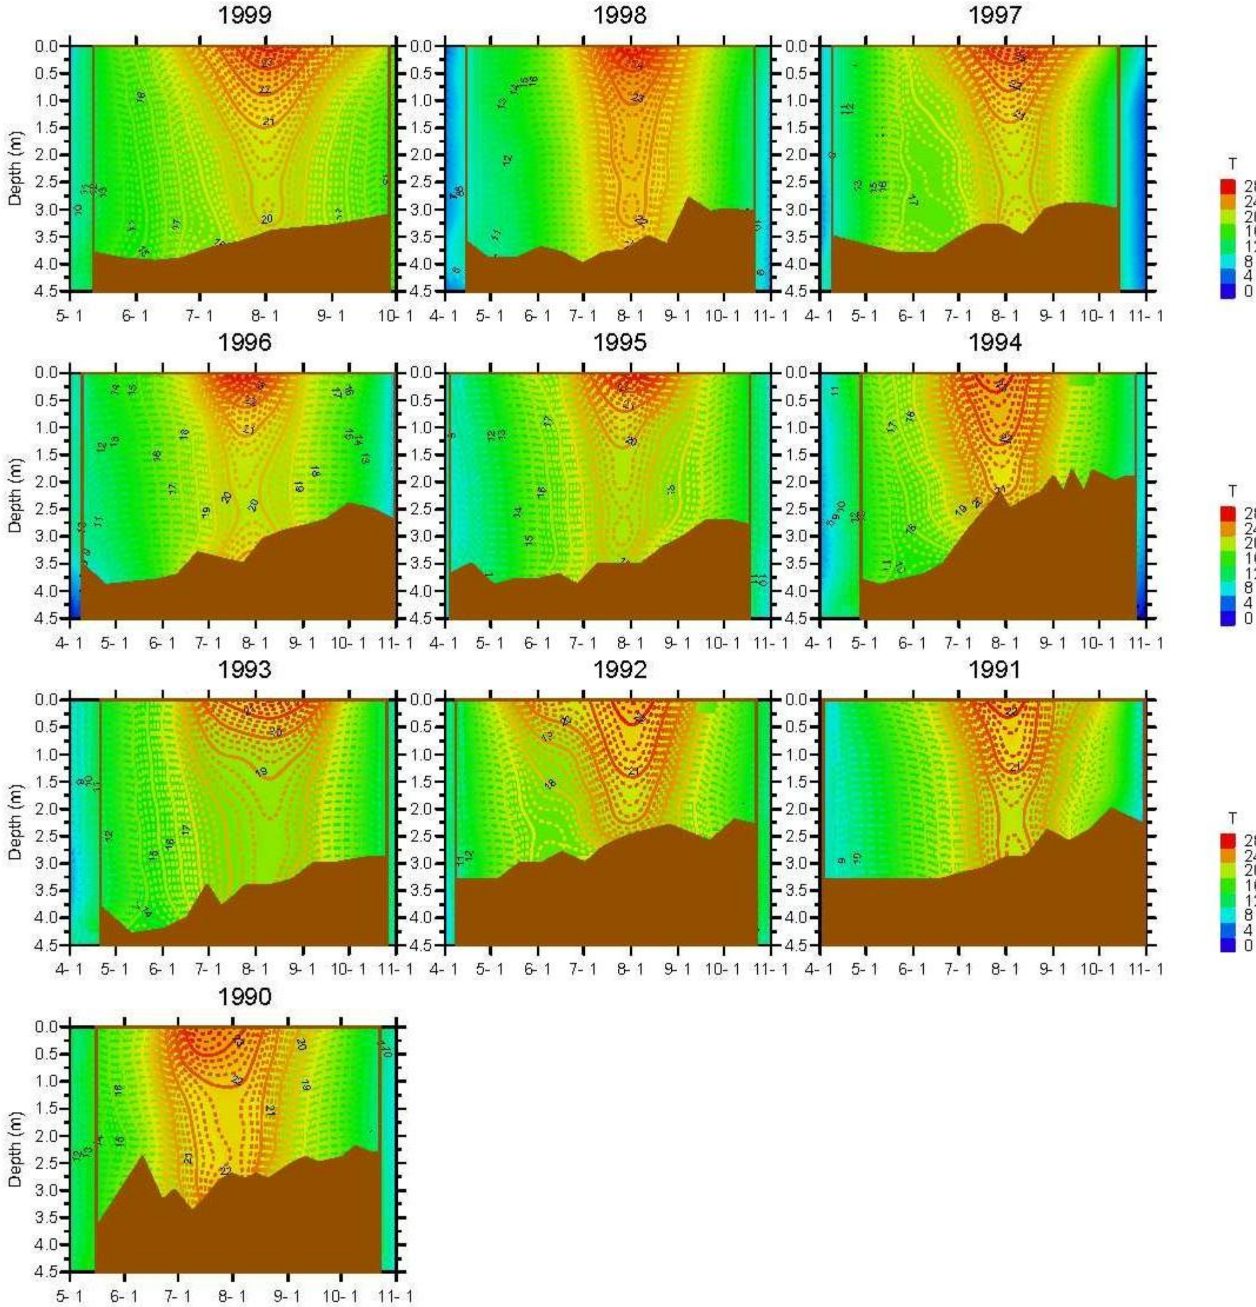
.



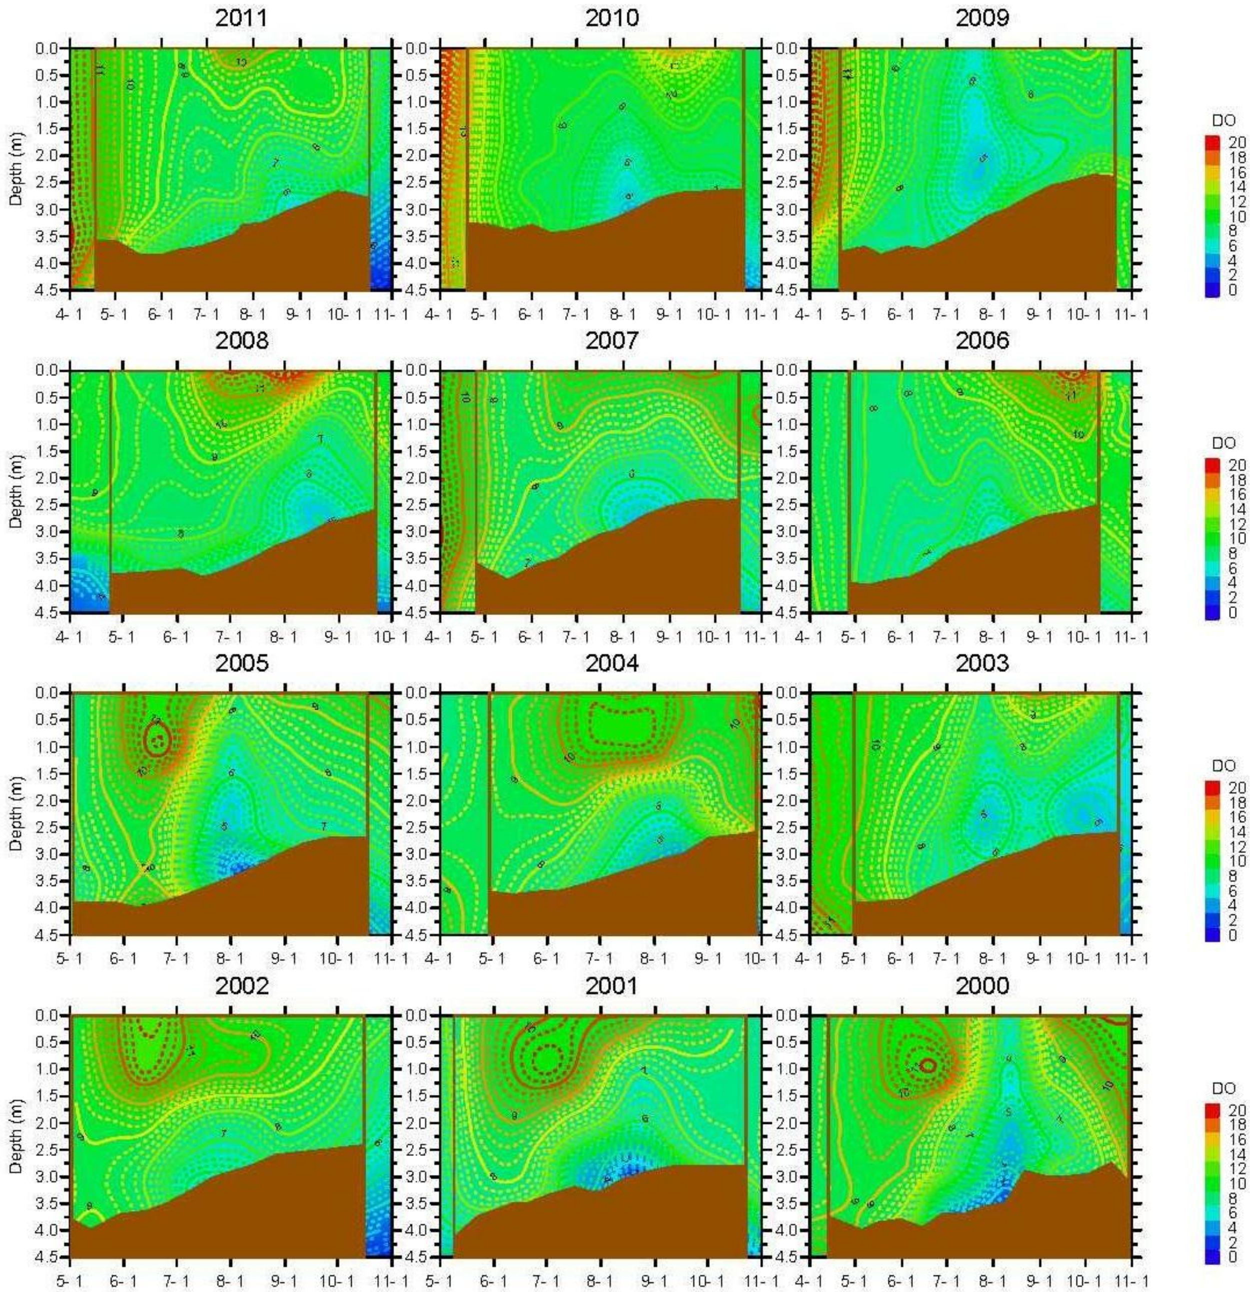
Depth-time distributions of isopleths of pH at UKL station Eagle Ridge (ER), 1990-1999. Note: 1) brown shaded area on the abscissa denotes the bottom profile depth, and 2) contours are not valid outside of vertical brown lines (begin and end dates for seasonal sampling).



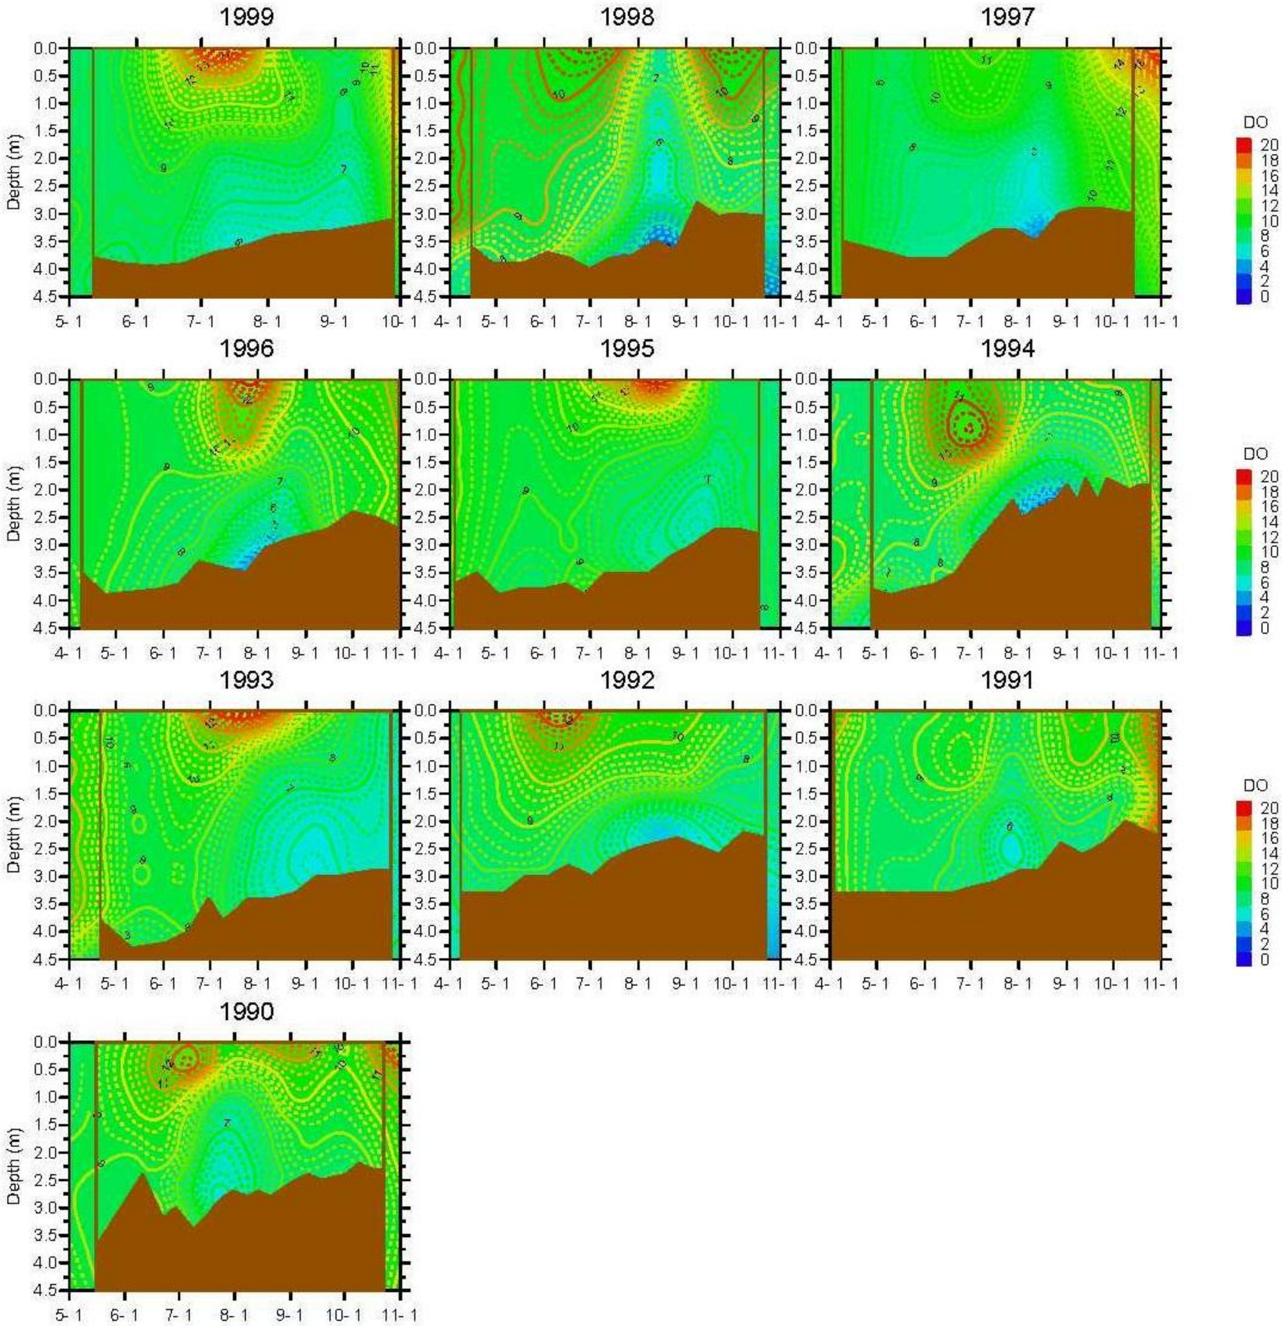
Depth-time distributions of isotherms of temperature (˚C) at UKL station Mid-North (MN), 2000-2011. Note: 1) brown shaded area on the abscissa denotes the bottom profile depth, and 2) contours are not valid outside of vertical brown lines (begin and end dates for seasonal sampling).



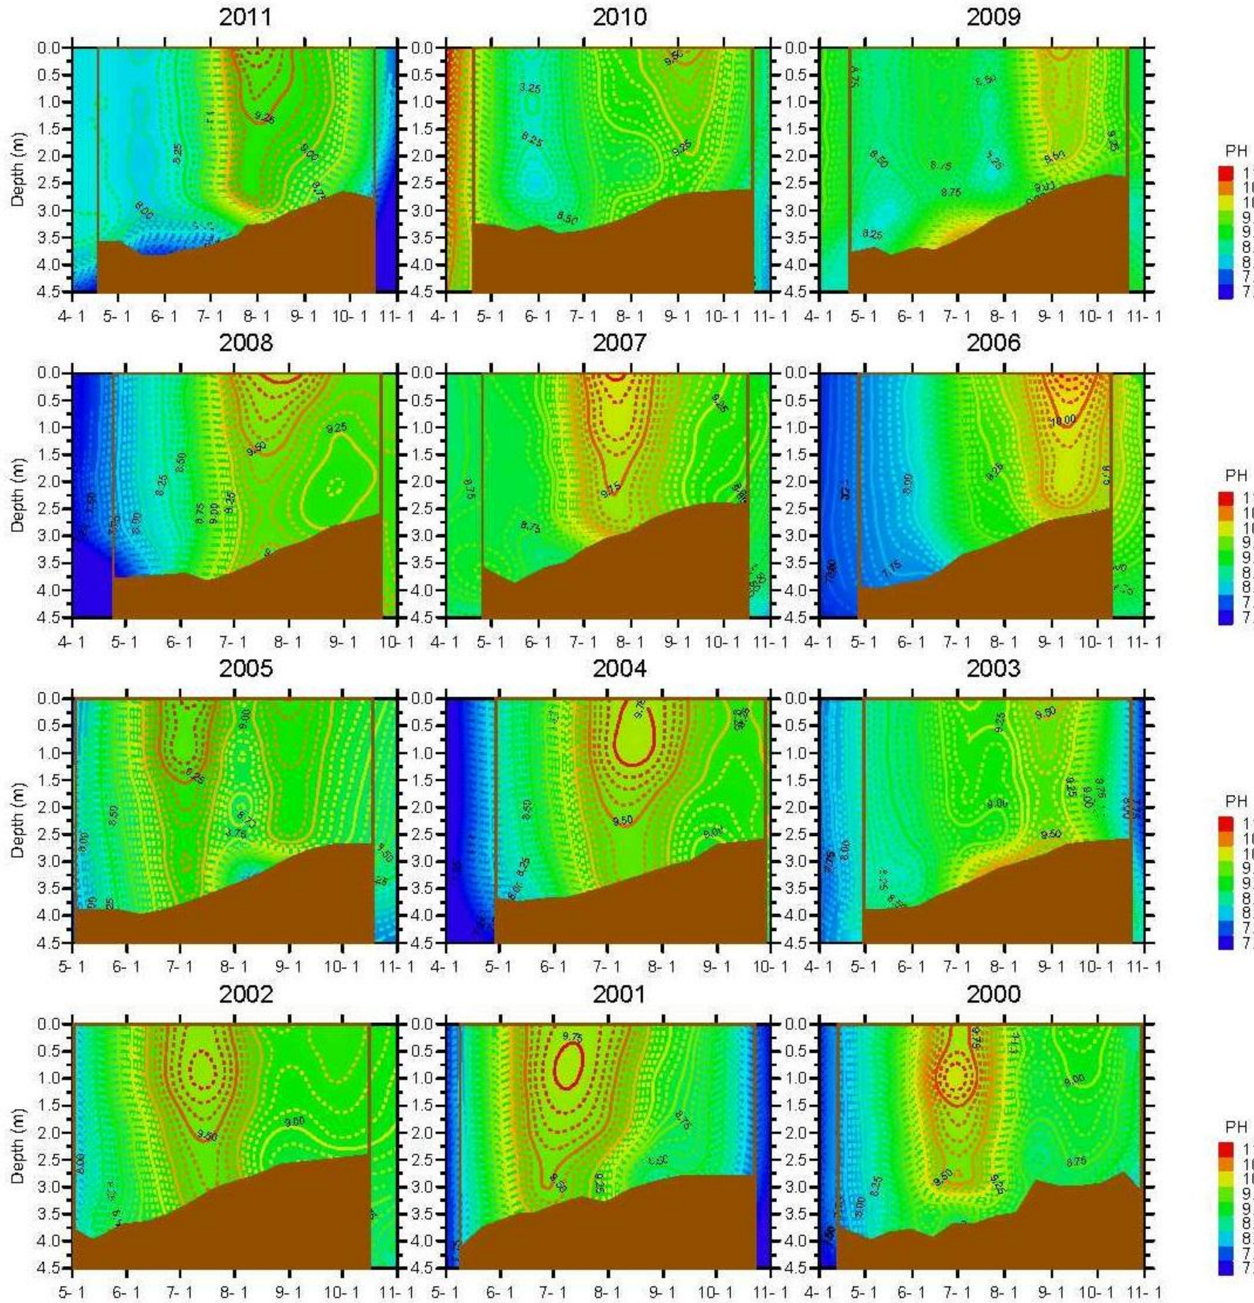
Depth-time distributions of isotherms of temperature (˚C) at UKL station Mid-North (MN), 1990-1999. Note: 1) brown shaded area on the abscissa denotes the bottom profile depth, and 2) contours are not valid outside of vertical brown lines (begin and end dates for seasonal sampling).



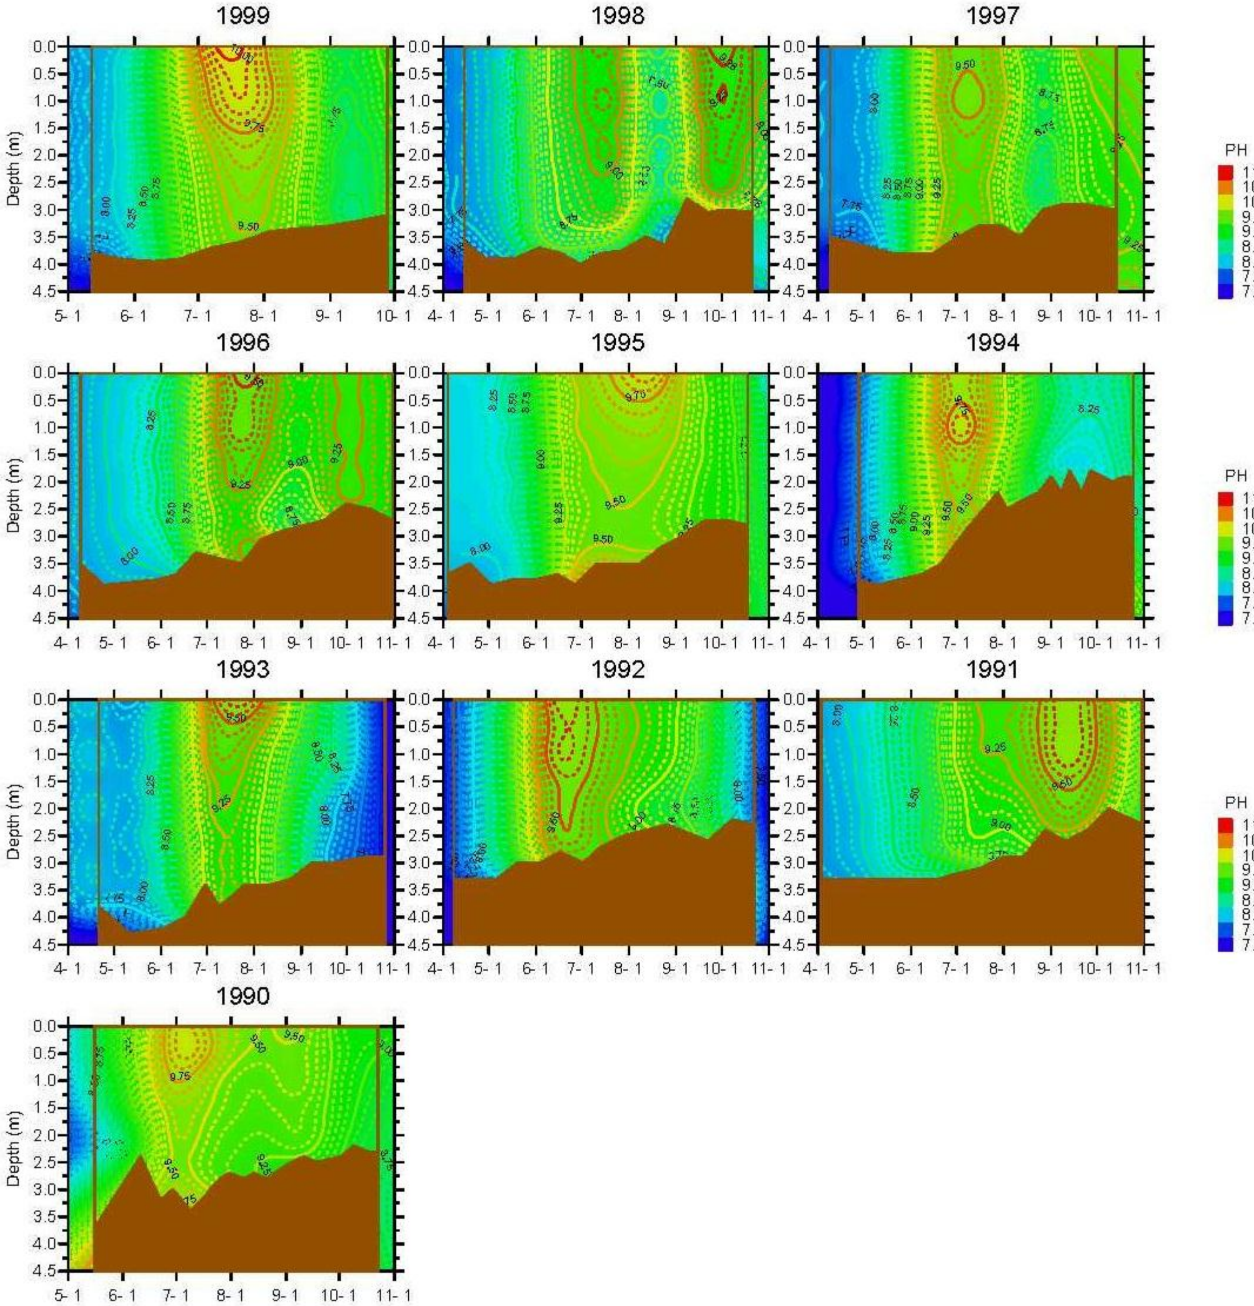
Depth-time distributions of isopleths of dissolved oxygen (mg/L) at UKL station Mid-North (MN), 2000-2011. Note: 1) brown shaded area on the abscissa denotes the bottom profile depth, and 2) contours are not valid outside of vertical brown lines (begin and end dates for seasonal sampling).



Depth-time distributions of isopleths of dissolved oxygen (mg/L) at UKL station Mid-North (MN), 1990-2010. Note: 1) brown shaded area on the abscissa denotes the bottom profile depth, and 2) contours are not valid outside of vertical brown lines (begin and end dates for seasonal sampling).



Depth-time distributions of isopleths of pH at UKL station Mid-North (MN), 2000-2011. Note: 1) brown shaded area on the abscissa denotes the bottom profile depth, and 2) contours are not valid outside of vertical brown lines (begin and end dates for seasonal sampling).



Depth-time distributions of isopleths of pH at UKL station Mid-North (MN), 1990-1999. Note: 1) brown shaded area on the abscissa denotes the bottom profile depth, and 2) contours are not valid outside of vertical brown lines (begin and end dates for seasonal sampling).

APPENDIX II: Summary statistics of monthly distributions for the June-September period, Upper Klamath Lake Stations; 1990-2011 (LQ= Lower Quartile; UQ=Upper Quartile).

Year	Month	Parameter	Temp-erature (oC)	pH	Dissolved Oxygen (mg/L)	Secchi Depth (m)	Chloro-phyll a (µg/L)	Total Phosphorus (µg/L)	Soluble Reactive Phosphorus (µg/L)	Total Nitrogen (µg/L)	NO3+NO2 Nitrogen (µg/L)	NH4 Nitrogen (µg/L)	Un-ionized Ammonia (µg/L)
